Motif Detection Using Numerical Data Optimization Technique in ECG Signals

Ramandeep kaur¹, Balkrishan Jindal²

¹Student of Yadavindra College of Engineering, Talwandi Sabo, Bathinda, Punjab (India)

²Assistant Professor, CE Section, Yadavindra College of Engineering, GKC, Punjabi University, Talwandi Sabo, Bathinda, Punjab (India)

Abstract- The motif discovery mechanism is used for the analysis of the ECG signal along with the efficient particle swarm optimization algorithm. In this method motif detection in the ECG signal sequences is presented. The proposed method is based upon the variable length of motif and detected the repetitive patterns in input ECG signal. This method has been visualized to analyse the signal data under the in-depth vigilant analytical method. Optimization of signals in the proposed method is performed by Particle Swarm Optimization technique (PSO) for improving the quality of signals. The data set used in this work is collected from the University of California, Riverside (UCR). The performance of the proposed method is measured using various parameters like Execution time, Precision, Recall and F1-measures. The performance of the proposed method is compared with existing methods in terms of accuracy and execution time. The Execution time and Accuracy of proposed method is in more improved form than the existing methods.

Keywords- Motif detection, Particle Swarm Optimization, ECG Signal analysis, Execution time.

I. INTRODUCTION

Electro Cardio Gram is a diagnosis device that represented the electrical activity of the heart. Electro Cardio Grams delivers the large amount of data relating with the physical position of the heart. The foremost necessary strategies are used in the analysis of cardiovascular problems. Heart related problems are the resultant of many disorders within the heart rate changes, irregularity, and position of origin or conductivity in internal organ which are in the form of electrical term [1]. Categorization in heart condition is a crucial phase in generating devices for observing the fitness of people [1]. Electro Cardio Gram (ECG) is device that is used for the treatment of heart diseases. The monitoring periods which are in larger size, there is the need of compressing is necessary for handling that type of data. This extends the volume of records wherever huge amount of signals are store for observing and evaluation.

he ECG feature abstraction method produces the important patterns that are utilized in the sequence spontaneous examination. The various approaches will be used in the discovery of these patterns. However, representing the signal in a better way or in compressed form is very much important. If any of the abnormality occur in the signal that signifies the heart problems [2].

Motifs are frequently recurrent subsequence's that represent interesting local patterns. These are discovered from the large series of data. The motifs are similar and dissimilar patterns of signals. Time series motifs, that square measure similar subsequence's or often time occurring patterns, have vital meanings particularly in medical domain[3]. Motifs are discovered that tell about the beat is normal or abnormal. These are generated for further analysis and classifications of numerical data. The motifs are produced more accurate results. The processing rates of motifs are high. These are more scalable. There are various types of motifs and standard motifs are produced for resulting output. Categorification of knowledge will be performed with the scientific analysis, operations related with business, and social media in the biggest knowledge field. The temporal records are consecutive and collecting over time, and are known as Time series [3]. Sequential time series data is a well-arranged list of occurrences. An event will be diagrammatical used a symbolic worth, a numerical real number rate, Vector of real values or a composite knowledge sort. The combination of global characteristics and local motifs are used to explain the information and feed machine learning algorithms. Particle Swarm Optimization (PSO) could be a procedural methodology that optimizes the various problems by iteratively performing actions. The attempts are performed to boost a contender results with respect to a given measure of quality.

- A. P ripple denotes the magnitude of voltage wave is in lower rate that signifying the depolarizing and shrinkage of the rightward and leftward atria.
- B. The transparent P ripple signifies the sinus pulse.
- C. Absence of P shape might recommend artery fibrillation, functional beat or chamber beat
- D. is terribly troublesomethe analysis of P wavelet of high SNR proportion in Electro Cardio Gram waveform.
- E. . QRS compositeis the biggest volt level deflection around 10mv.
- F. Twentymilli Volt however might variation in magnitude depends upon age, and gender. The V magnitude of wave shape might additionally offer data regarding the cardiac disease
- G. Period of the QRS composite specifies how much time required by the ventricles to modify and should provide data regarding conduction issues within the ventricles
- H. Largest T ripple might specify the Hyperkalaemia and ischemia.

II. RELATED WORK

Liu et al. [3] explained the Motif detection method for large scale statistics (MDLats). Finding the pattern in time series thenthistechnique is used to eliminate the redundancy. This technique worked with the exact and approximate algorithms in the detection of better motifs. The Symbolic Aggregate Approximation (SAX) and Piecewise Aggregate Approximation (PAA) algorithm has been used in the detection of sub sequences.

Harvey et al. [4] explained the automatic features detection for numerical series by using the Genetic technique. Designing of features performed by using various approaches such as Model based, Distance based or Similarity based approaches. Autofead mechanism was used for the automated features. Autofead has the ability to reduce the large features into minimal form of features. In this method, the fitness of population has been calculated by applied various optimum values of parameters.

Melgani et al. [5] explained the classification system of PSO-SVM. Particle Swarm Optimization is used to improve the performance rate of the Support Vector Machine classifier. The SVM classifier has been optimized for finding the best parameter value that used with the discriminant function. On the basis of ECG data the experiment was performed. The dataset taken from the MIT-BIH database. The normal and abnormal beats find out in this. For the comparison, the two reference classifiers has been used i.e. K Nearest Neighbour classifier and Radial basis function neural network classifier.

Wang et al. [6] explained the work on the bag-of-words or pattern of ECG data representation for medical specialty time series classification. In this work, the Artificial Neural Network (ANN) and Probabilistic Neural Network (PNN) classifier was used. Time series patterns represented in the form of histograms. The proposed technique treats a statistic as a text document and extracts native segments from the time series as words.

Yasser et al. [7] described the problem of Constrained Motif Detection using two approaches. MC-Full and MC-Inc has been utilized for solving the constrained motif detection issues in a more effective way. In this, unconstrained motif finding issues are converted in the constrained by applying the change-point detection procedure. The Robust Singular Spectrum Transform compared with ancient Singular Spectrum Transform by applied artificial and real group of data.

III. PROPOSED METHOD

In this paper, the optimization of ECG signal is performed based on Particle Swarm Optimization. The implementation of the Particle Swarm Optimization algorithm takes place for the precise length of the motifs. By using the optimizing approach, the burden on data communication links will be decreased. The proposed method will be designed to overcome the shortcomings of the existing method. The overall performance of the optimization method based upon PSO algorithm is observed in the form of various parameters like Precision, Recall and F1-measure etc. The following equations 1 and 2 described the overall working of the PSO to observe the pbest and g best value of all solutions in the iterative manner. The flowchart of the proposed method is shown in Figure-2

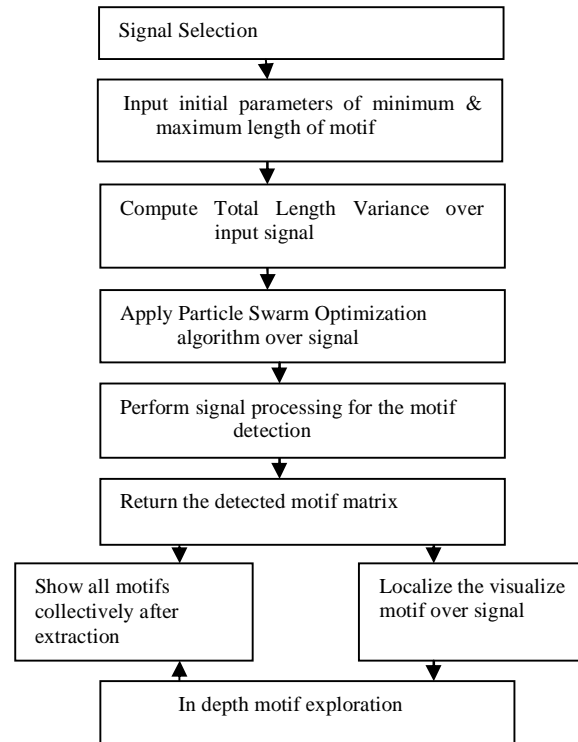

Figure -2: Flowchart of proposed method

A. Proposed Algorithm

- 1) Step-1: Select the particular ECG signal from the UCR data set.
- 2) Step-2: Input initial parameters of minimum and maximum length of motif.
- 3) Step-3: Set the threshold value for the motif
- 4) Step-4: Compute the total length variance over the signal.
- 5) Step-5: Evaluates the fitness value of all signals
- 6) Step-6: If fitness value recorded higher than personal best value of solutions obtained on other rounds.
- 7) Step-7: Then update the current PBest as the global best value (g Best).
- 8) Step-8: Elect the best p Best value in all of the iterations as the global best observed on all iterations in the system
- 9) Step-9: Observe the velocity of the signals according to the equation (1).
- 10) Step-10: Shifting the position of the signals according to the equation (2)
- 11) Step-11: If the termination criterion is not satisfied then again calculates the fitness value of signals
- 12) Step-12: Motifs are detected.

$$q[i] = q[i] + CL1 * rand() * (pB[i] - pR[i] + CL2 * rand() * gB[i] - pB[i]) \quad (1)$$

$$pR[i] = pR[i] + q[i] \quad (2)$$

Where $q[i]$ is denoted the signal velocity, $pR[i]$ provides the present output for signals that are hold in a random way. $pB[i]$ and $gB[i]$ are locally and globally best fitness ranks for every signal correspondingly. $rand()$ is a random number between (0, 1). $CL1$, $CL2$ are learning elements.

B. The proposed method shows the main three loops of the algorithm.

- 1) **Motif Detection using the Total Length Variance (TLV) method.**: Acquisition of the ECG signals take place. The size of signals taken in the form of arrays or in the form of number of rows and columns. Then the initialization of values performed. After this initialize the window size. The size of window is depends upon minimum motif length then run the iterations equals to the

Total Length Variance (TLV). The signal is acquired according to the length of the signal. Then extracts the values of the signal which are fetched. Then apply the sliding window analysis to find the fittest pattern in the input window. After this finding the pattern of signals in the given data whose value not exceeding the TLV. If that type of pattern is found. Then mark the position of the detected motif. Obtain the motif length then add the position to the position array and add the motif length to length array. The computation of squared distance performed for the classification of the pattern. After this update the best pair for length. Return the motif length and position list.

- 2) *Signal processing for the motif detection.* Read the selected ECG wave signal and converted into the vector form. After this computing the signal drift using the drift error evaluation. The return of drift vector which is equal with the length of the ECG signal. Then eliminate the drift from the original signal. There is the drift free signal is returned. Then assess the degree of fitness over the signal after the elimination of the drift. Then run the iterations according to number of blocks in the input signal. Input the degree of polynomial up to fourth order then calculate the least squares and the polynomial value. Get the fittest polynomial coefficients then the shift of each signal block according to the evaluated value. If that is the last iteration then return the signal. Then analyse the R-peaks by utilizing the early stage detection with the usage of relative gradient. In the block based manner, Analysis of the signal coefficients of each curve of the motif. Then determine the RR interval between the two R peaks. Identify the first R wave in the signal. Enlist and mark each R wave after the classification of first R wave. Then finish the iterations after identifying the last R wave using the decision rule. Identify the false negative cases. Delineate the sub-signal region in the false negative case by employing the change of slope rate for false positive case elimination. Then apply the median filter once again. Eliminate the base line drift from the final signal.
- 3) *Detection of motif using cross-correlation and variable threshold.* Input the signal data with the length of N-entities, step size between the ranges of 0.04 seconds to 0.12 seconds. Then initialize the threshold values for the motif discovery. Find the initial motif according to the input threshold value. After this find out the numerical sequence within the given range by defining the alternative range formed from threshold. Then finalize the training motif length according to the initial pattern discovery. Find out the maximum amplitude pattern in particular window and after that assign the pattern to the training motif data. Find autocorrelation between the signal and training motifs. Then return the detected motif data matrix and motif locate.

IV. RESULTS AND DISCUSSION

The results of the proposed method are presented and discussed. The proposed method is analysed with data set of ECG signals from the University of California, Riverside (UCR). There are 200 ECG signals are used for the analysis. The implementation is performed in the Matlab. The ECG data is the continuous data, which arises every second and received in the fixed length of segments.

The execution time for the motif detection has been recorded in milliseconds for each entry. The proposed method has been tested upon the ECG datasets for the performance evaluation of the motif detection in the terms of Precision, Recall and F1-measure etc.

A. Elapsed Time

The elapsed time is the parameter, which records the overall time taken to perform a specific task. The elapsed time is recorded by measuring the difference of finish time and start time, which can be defined with the following equation:

$$\text{Elapsed time} = \text{Finish time} - \text{Start time} \quad (3)$$

B. Precision

The precision is the case giving the statistical accuracy by computing the accuracy against the false positive results. The false positive results represent the false matches produced by the classification algorithm. The precision value predicts the impact of the false positive cases and returns the accuracy of the positive cases. The precision is also known as the sensitivity and elaborated with the following equation:

$$\text{Precision} = \text{True} \frac{\text{positive}(TP)}{\text{True}} \text{Positive} + \text{False Positive} \quad (4)$$

C. Recall

Recall is the performance parameter, which computes the true positivity of the results against the false negativity. The recall parameter gives the results by computing the following equation:

$$\text{Recal} = \text{True} \frac{\text{Positive}(TP)}{\text{True}} \text{Positive}(TP) + \text{False Negative}(FN) \quad (5)$$

D. F1-Measure

The F1-Measure is the cumulative parameter to assess the overall impact of the precision and recall, to study the overall impact of the false positive and false negative cases over the overall accuracy assessed from the preliminary statistical parameters. The F1-score value is represented in the range of 0 to 1 or 0 to 100, decided as per the maximum ranges of the precision and recall. The following equation is utilized to measure the F1-measure:

$$f1 = 2 * precision * \frac{recall}{precision} + recall \quad (6)$$

- 1) *Time Oriented Analysis*: The proposed method has been analysed for the elapsed time as it becomes the important factor while processing the ECG data discovers the motifs in the given signal set. The proposed method is aimed to improve the elapsed time parameter and has been done better than the existing methods on nearly all of the iterations. The motif discovery has been performed in the minimum time. The proposed method has been analysed for the elapsed time as it becomes the important factor while processing the ECG data discovers the motifs in the given signal set. The proposed method is aimed to improve the elapsed time parameter and has been done better than the existing methods on nearly all of the iterations. The motif discovery has been performed in the minimum time
- 2) *Accuracy Oriented Analysis* :The proposed method has been also analysed under the various accuracy oriented parameters, which includes the Precision, Recall and F1-measure. The proposed method has been performed up to the mark as per recorded in the results table. The proposed method represents the variations studied in the Table 2. The proposed method has been found with the value of 89% for recall, 95% for precision and 90.50% for the F1-measure when analysed with the lower bound limit of 80 and upper bound limit of 110. The results of lower bound value of 90 and upper bound of 120 produces the 94% precision,92.30% recall and 93% F1-measure, which is adequately acceptable for the case of motif detection.
- 3) *analysis of proposed method with existing methods*Analysis in the terms of execution time

The time oriented analysis has been conducted for the comparison of the proposed method with the Brute Force, Moen Keogh, RP-1, RP-2 and MDLats.

Table- 1

Comparative analysis of the proposed method with Brute Force, Moen Keogh, Random Projection- 1, Random Projection- 2 and MDLats in terms of elapsed time at different threshold values.

iterations	Execution time (ms)					
	Brute force [3] eh=80 el=40	Moen Keogh [3] eh=80 el=40	Random projection 1 [3] e=80	Random projection 2 [3] e=40	MDLats [3] eh=80 el=40	Proposed method eh=80 el=40
1	40098	6124	680	783	702	665
2	41522	6843	678	765	670	662
3	49172	6057	669	770	671	663
4	48074	6280	692	778	701	682
5	48270	6081	670	786	676	673
6	48399	6372	674	762	688	672
7	47832	6751	671	789	678	662
8	48407	6306	687	781	697	671
9	48259	6991	690	792	712	676
10	48069	6623	660	776	677	663

The proposed method has outperformed all of the methods in the comparative table with marginal differences. There are 10 iterations performed in this. In the each iteration, the proposed method has different execution time. The elapsed time is in the more

improved form than the existing systems. The proposed method ranges between 662 and 682 milli-seconds, whereas the nearest contender Motif Discovery Method for Large Scale Time Series (MDLats) has been found performing between 670 and 712 milli-seconds. The running time of each algorithm is recorded in the table and each algorithm is run ten times, the matrix threshold value is set in each algorithm. The value of threshold is denoted by e . e_l denotes the lowest threshold value and e_h is the highest threshold value. According to the threshold value every algorithm works. Results of the Random Projection (RP-1), RP-2, Motif Discovery Method for Large Scale Time Series (MDLats) and the proposed method are shown in Figure 2 with same dataset. From the experimental results it has been concluded that the proposed method is better than RP-1, RP-2 and MDLats methods in the terms of execution time. The proposed method has been found marginally better than the time oriented values of RP-1 and MDLats which shows the marginal differences nearly during all of the iterations to mark the significant improvement.

Figure 3: Comparative analysis of the proposed method with RP-1, RP-2 and MDLats in term of execution time.

Table-2

Comparative analysis of the proposed method with Random projection method and MDLats method in terms of Precision, Recall and F1-measure.

Gun-point	Random projection method [3]			MDLats method [3]		Proposed method	
	$e=100$	$e=90$	$e=80$	$e_l=80$ $e_h=110$	$e=110$	$e_l=80$ $e_h=110$	$e_l=90$ $e_h=120$
Precision	0.93	0.83	0.85	0.92	0.92	0.95	0.94
Recall	0.86	0.86	0.89	0.9	0.84	0.89	0.923
F1-measure	0.894	0.845	0.87	0.91	0.878	0.905	0.93

The accuracy oriented results show the significant improvement in the proposed method, which has been compared against the two nearest contenders on the basis of the variable upper bound and lower bound ranges. Comparison with Brute Force and Moen Keogh is not feasible on the basis of accuracy. The proposed method has been found efficient in the terms of precision, recall and F1-measure parameters. From experimental results, it has been concluded that the proposed method is better than Random projections and MDLats in terms of accuracy in the Figure 3. This shows the variations between the proposed method, MDLats and Random Projection methods during the comparative analysis.

Figure 4: Comparative analysis of the proposed method with Random projection and MDLats in terms of Precision, Recall and F1-measure.

V. CONCLUSION

In this paper, the study of the motif detection in the ECG signal is presented. Motif discovery mechanism is used for the analysis of the ECG signal based on Particle Swarm Optimization Algorithm. The proposed method improves the detection rate of motifs and the load on the data communication links also reduced. The elapsed time is also improved. In the smaller time periods, the normal and abnormal beats are detected. Particle Swarm Optimization necessitates only primitive and basic mathematical operators as compared with existing techniques; it is computationally cheap in terms of both memory and runtime.

The proposed method has been found efficient in discovering the motifs within the significantly lower time, as it has been recorded with the time span of lower than 686 ms on all of the iterations, which was average motif discovery time for the existing method in the ten iterations. By using the suitable parameters and Particle Swarm Optimization Technique, the proposed method gives better results than the existing techniques.
