Analysis of Wildfire Detection using CNN Model

Akshatha V¹, K R Sumana²

¹PG Student, The National Institute of Engineering, Mysuru, Karnataka, India

²Assistant Professor, The National Institute of Engineering, Mysuru, India

Abstract: Forest is viewed as one of the most significant and essential asset. It is an enormous surface of region loaded up with trees, bunches of dried leaves, woods, etc. These components support the fire when it begins. The fire can be lighted through many reasons, for example, high temperature in summer seasons, smoking, or firecrackers. When fire begins, it will stay until it recognized totally. The harm and the expense for recognize fire in view of wild fire can be decreased when the fire distinguished right on time as could be expected. Thus, the fire discovery is significant in this situation. There are various kinds of fire location techniques utilized by the Government specialists, for example, satellite observing, tower checking, utilizing sensors, optical cameras, etc. In any case, these strategies actually have a few disadvantages in distinguishing the beginning phase of the fire. In our project, we propose an original framework for distinguishing wildfire utilizing Convolutional Neural Networks (CNN). CNN and a classification network, named ResNet50 is used as a feature extraction network to achieve rapid and accurate extraction of image feature information.

Keywords: Convolutional Neural Networks, ResNet-50.

I. INTRODUCTION

Wild fires involve concern since they make broad harm climate, property and human existence. The Wild flames has turned into a danger to not exclusively to the timberland riches yet in addition widely varied vegetation and nature of the climate of the district.. High climatic temperature, easing up and dryness offer positive climate for a fire to begin which are the regular reasons for woods fire. The fire is additionally brought about by Man-made sources like bare fire, cigarette, electric flash, and so forth . Fierce blaze represents an incredible danger as they stay inconspicuous for a significant stretch till the impacts comes to city. Consequently, it is important to find out the wild fire at a previous stage The errand of checking the timberlands is troublesome on account of the tremendous domain and thick backwoods. In our project we are utilizing CNN calculation which can be utilized to distinguish or foresee such perils.

II. LITERATURE SURVEY

- 1) At early times, Wild fires were identified utilizing watch towers ,which were not effective on the grounds that they depended on human perceptions. In late a Wildfire recognition strategies have been carried out, for example, watch towers, satellite picture handling techniques, etc. Despite the fact that there are numerous downsides, for example, inefficiency, power utilization, dormancy, precision and execution costs. To overcome this, wild fire identification framework utilizing remote sensor networks is proposed in this paper. Remote sensor organizations (WSNs) are self-designed and foundation free remote organizations that assist with checking physical or natural circumstances and pass these information through the organization to an assigned area or sink where the information can be noticed and dissected. Proficiency and low power utilization are the significant benefits of a WSN. In this paper, machine learning regression model was utilized alongside limit proportion for investigation process.
- 2) This study presents a profound learning structure called Fire-Net, that is prepared on Landsat- 8 symbolism for the identification of dynamic flames and consuming biomass. In this they meld the Optical(red, green and blue) and warm modalities from pictures for a successful portrayal. For the detail evaluation of Fire-Net's effectiveness 5 AI calculations are used. They are KNN (K-Nears- Neighbor),SVM(Support Vector Machine),MLP(Multi-Layer Per-ceptron,RF(Random forest)and Extreme Gradient Boosting(XGBoost) are utilized for fire identification results. This project shows the general precision of 97.35% and furthermore having the option to recognize little dynamic flames. Moving during the entire mission time frame.

III. PROPOSED WORK

This project is an attempt to use convolutional neural networks (CNN) to detect the presence of a forest fire in an image. The idea is that this model could be applied to detect a fire or a start of a fire from image of a forest. The model could be applied in real-time to low-frame rate image gives indication about fire and no- fire.

IV. METHODOLOGIES

In our project we are using 3 modules Admin, User, Forest Officer . In admin module admin can login through the valid email id and then admin can add Forest Officer. Also admin can view the details of user, forest officer and user query. In User module user must register by giving personal details like name, age, phone number ,date of birth, email id and desired username & password . Then user login through their valid email id and password and user can send the queries to forest officer .In Forest Officer module Officer must login through email id and password and Forest Officer can view the user can view the user details, user queries and respond to the user queries.

A. Deep Learning

Deep learning is the only subset of machine learning that prioritizes teaching the computer about human primal impulses. A Computer algorithm teaches itself to carry out classification tasks using deep learning on complex data in the form of images, text, or sound. State-of-the-art (SOTA) accuracy may be attained by these algorithms, and on rare occasions, they can even beat human performance. Deep learning may be conceptualized as an automated kind of predictive analytics at its most basic. Deep learning algorithms are piled in a hierarchy with progressively higher levels of complexity and abstraction than conventional machine learning algorithms, which are linear.

B. Convolution Neural Network

Convolutional neural networks are special kind of artificial neural network that can mimic the human brain activity to analyze data with supervised learning. CNN is modified multilayer perceptron, which means fully connected network. It consists of several layers namely, input layer, output layer and many hidden layers to make it happen. These hidden layers are convolutional hence the name convolutional neural networks.

Step-1: Import key libraries.Step-2: Reshape the data.

Step-3: Normalize the data.

Step-4: Define the model function.Step-5: Run the model.

Fig. 1 Flowchart of the CNN Algorithm

C. Dataset

Since the data is not publicly available for the forest fire data set, we used data from the Internet. Data is in the form of images. Following that, the images with and without fire are saved as, accordingly. Then the set of data is splited into a training set and a test set. This is done carefully because inaccurate data will distort the neural network's results and prevent it from producing an accurate system.

D. System Architecture

In this project we are using images as dataset .After collecting datasets they are passed to the data Pre- processing unit in which the datasets are splits for training and testing each. After that we are extracting features from the image. Then we make use CNN algorithm for classifications and test the valid datasets, using the algorithm we are building the model. And we will get the output as fire or no fire.

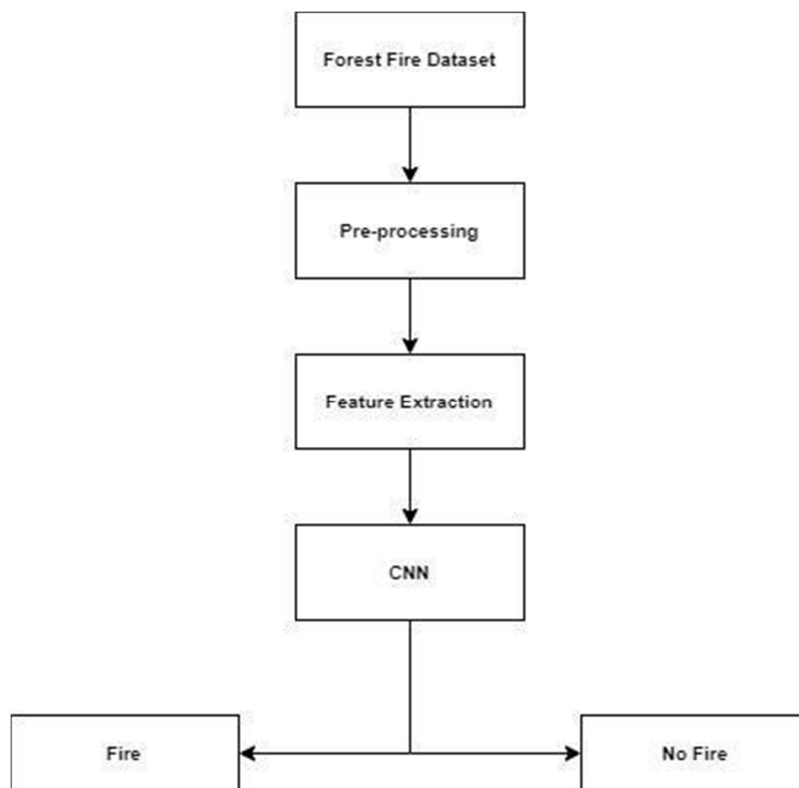

Fig. 2 System Architecture

V. RESULT ANALYSIS

In the below figure Fig 3 shows the misfortune bend of the training set of the forest fire image. The blue line demonstrates the trained loss and orange line shows the valid loss. It is seen that the quantity of cycles is around 50,the worth of misfortune capability has balanced out and doesn't come up short.

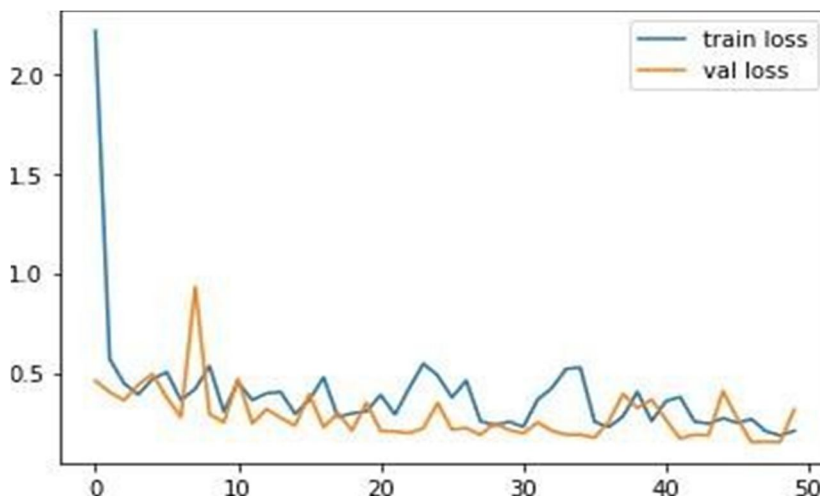

Fig. 3 Loss curve of the training set

In the below figure Fig. 4 shows the accuracy curve of the training set of the forest image. The blue line indicates the trained accuracy and orange line indicates the valid accuracy. It is seen that the number of iterations is around 50, the forest image accuracy rate reaches more than 90% .

Fig no 4- The accuracy curve of the training set.

In the below figure Fig 5 shows the wild fire being detected in the selected image. First the users should choose the image from which he /she has to detect the fire is present or not .Then selected image will be displayed and then the user has to click on the identify button then the result will be displayed on the next column. In the below image fire is detected in the image so in the result column the result is displayed as Fire detected from selected image.

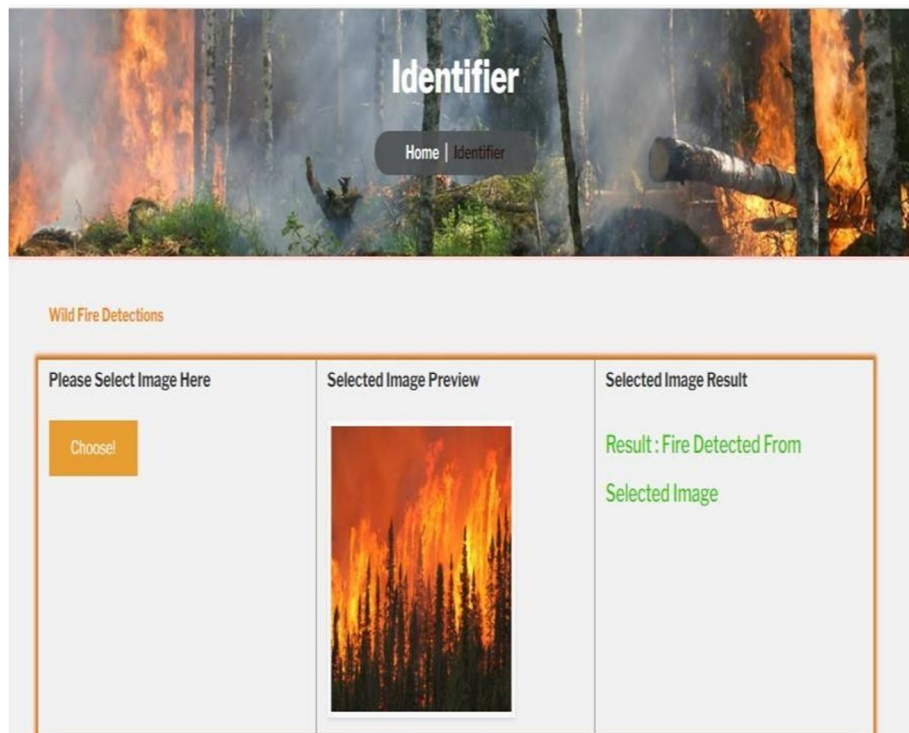

Fig no 5-Wild fire detected in the selected image

In the below figure Fig 6 shows the wild fire is not present in the selected image. In the below image fire is not detected in the image so in the result column the result is displayed as Fire not detected from selected image.

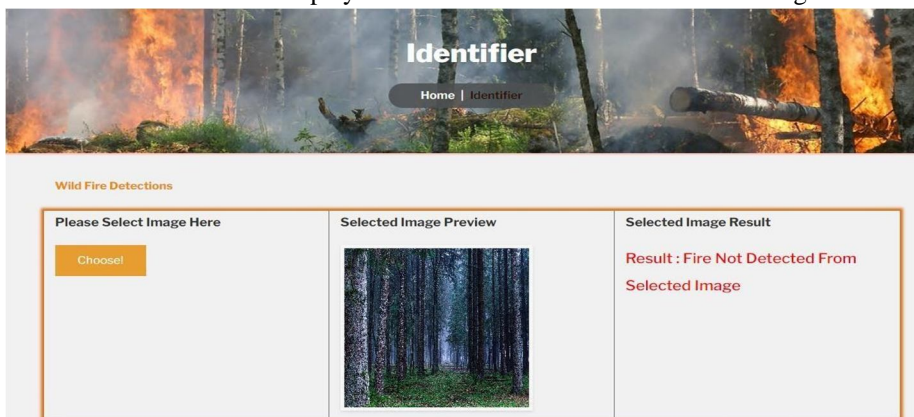

Fig no 6 – Wild fire is not present in the selected image

Epochs are the total number of cycles used to train the machine learning model using all of the training data. All training data is utilized precisely once in Epoch. The total number of trips an algorithm has made around the training dataset is another way to think of epoch, or the time between two events. In training, a pass was considered to be one pass if it was both forward and backward. A machine learning model typically needs a small number of Epochs to be trained. Iteration and an epoch are typically used synonymously. How many times you go through your training set is indicated by the number of epochs. Since the model is changed each time a batch is processed, it may be modified more than once in a single epoch. The model is updated once every epoch if batch size is set to the length of x.

Epoch	Time	Loss	Accuracy
2	299s 14s/step	2.2140	0.5439
3	195s 10s/step	0.5698	0.7163
49	219s 11s/step	0.2072	20.2356
50	133s 17s/step	0.1860	0.9342

Table 1 Epoch Iteration

VI. CONCLUSIONS

In the dry environment, wild fires are a sort of catastrophic event that can happen without any problem. Our project can recognize Wild fire situations, from the underlying occasion (no fire) to fire discovery. The process of detection of wildfire in image reorganization algorithm based on CNN is present. The Resnet-50 model is introduced. It is shown that the proposed algorithm has high accuracy rate and is feasible. This framework will be very great at staying away from false alarm. The proposed forest picture order network involving ResNet-50 as a component extraction structure, according to trial discoveries, this organization performed well concerning characterization exactness for forest. The findings of the project are greatly satisfying. The model detected fire with accuracy rate of 93%.
