Database Security using Cryptography

Yash Singhal¹, Adwit Agarwal², Shivank Mittal³, Shrishti Katyayani⁴, Amit Sharma⁵

^{1, 2, 3, 4, 5}Department of Information Technology, Inderprastha Engineering College, Ghaziabad, India

Abstract: *There has been an explosion in data since last two decades and this explosion of data is due to high rates of data conversion and better internet services worldwide [21]. All the conventional methods of data handling have been replaced by much more sophisticated means. One of the typical shifts of the emerging information society is that information is becoming a crucial if not the most vital source. Information contrasts profoundly from further resources; for example and it can be imitative without cost, it can be erased without leaving traces. [22] Protecting the new resource information is a major issue in the information economy [20]. One such means is a Database. It makes it easier for data related queries but it can be dangerous if this data is leaked or sent outside the organization. A high price is positioned on confidentiality when information concerning states secrets, business plans, war strategy, medical records and financial transactions needs to be stored or transmitted. Since its inception, the Internet has enabled [19]. A cyber crime emerging in recent years data breach is one of the most notorious and disastrous data crimes majorly caused due to unsecure database. To secure these databases we can apply the concepts of AES algorithm. It is an algorithm used in cryptography which changes normal text to unreadable or cypher text.*

Keywords: *Cryptography, AES, cypher, digitization, confidentiality*

I. INTRODUCTION

There are wider range of internet applications in the modern world. There are various organizations that need intense information security such as Government Agencies, Financial Institutions, law enforcement etc. They need modern crypto algorithms to make sure that their confidential information is safe and secure and can't be accessed by any third party. All Cryptosystems use either Symmetric or Asymmetric encryption. [8] Symmetric Encryption requires only one Cryptographic key for encryption and decryption and is considered faster as compared to Asymmetric Encryption whereas Asymmetric Encryption consists of two cryptographic keys namely: Public key (which is disseminated key) and a private key (which is known only to the author). DES, Triple DES, AES algorithm etc. are some of the examples of Symmetric Encryption. Diffie-Hellman, RSA algorithm are few of the examples of asymmetric algorithm [4].

There are various incidents of data breach. A data breach incident is a security incident in which a third party or person obtains access to the information which had to be confidential. As per reports, India positions 3rd in the world in relations of number of data breaches. A whole of 86.3 million users information breached till November 2021. India showed an increase of almost 300 times in affected accounts compared to previous quarter. It states that approx 1 billion email accounts have been uncovered in both the years 2020 and 2021. Till November 2021, 952.8 million accounts were penetrated, which means that 1 out of every 5 population were affected worldwide [5]. So, a strong and reliable key management process is essential to prevent access to unauthorized access to sensitive data and information. Performance, strength of algorithm, data access, data type, community acceptance, cost, and key management should all be considered in order to choose the most suitable resolution [6].

Ensuring a suitable level of protection to database content affects the overall security model. Even though encrypting the data provides important protection, there are implementation decisions that affect the encryption process. These factors may be where will be the encryption of data would take place, what type of encryption algorithm is used, how well the encryption keys are managed [14] and protected, etc. In conventional client server-based encryption, the data is encoded using a server key or a client key in the database. There will be a constant vulnerability if there is a weak key at any end. In both the cases, the most important issue is the loss of the key used in the encryption process [7]. If the key is lost all the data is lost.

In this research paper, we will be mainly focusing on AES Algorithm. With an increase in computing power a vulnerability against certain key searches were found. Triple DES was created to overcome this problem but it failed. It is found about 6 times faster than the triple DES. It has 128-bit data, 128/192/256-bit keys. It can be implemented in Java and C. It is based on 'substitution-permutation network'. [3] It contains a series of related operations, few of which comprise swapping inputs by confident [18] outputs (substitutions) and others involve shuffling bits around (permutations). Surprisingly, AES performed all its computations on bytes where other conventional algorithms extensively used bits for their operations. AES treats the 128 bits of a normal text [2] block as of 16 bytes. These 16 bytes are organized in 4 columns and 4 rows for handling a form of matrix.

II. LITERATURE REVIEW

The word cryptography comes from the word Cryptos, which means hidden words and Graphen which have the meaning of writing, so the word cryptography can be interpreted as an art or science that examines how data is converted into certain forms that are more specific and difficult to understand by others. Cryptography has the purpose of being able to maintain the confidentiality of information or data that must not be known by others who have no interest in the information or data. Much work has been done related to this field of Cryptography. [13] Prior relational database cryptography research considered the encryption and decryption process of fields in accounts using Symmetric Encryption and Asymmetric Encryption. Recent research papers show that various research has been done in the area of Database as a Service (DAS). The main reason behind these research is to encrypt the database so that our information can't be accessed by any third party and only a set of authorized and desired users have the access to that database.[25] Approach proposed by Mykletun and Tsudik familiarizes a server coprocessor also known as SC, which is hardware with a processor, an input device, a backup battery, protected memory, and a tamper proof container. A server coprocessor is installed on the server which supports all the ongoing cryptography operations. The client can communicate with the server coprocessor with the help of a secure channel. A model was proposed by the authors and developers to counter DOS attacks but the bigger problem was still not addressed.

Database encryption allows a business house or an enterprise to secure data as all the query operations are taking place in the background. Database-level encryption defends the data within the DBMS and also guards against a inclusive range of threats, including storage media theft, well known storage attacks, database-level attacks, and malicious DBAs. All the application-based models are eliminated by Database-level encryption. While this solution can certainly safeguards data, it does want some integration work at the database level, comprising alterations of existing database schemas and the use of triggers [1] and stored procedures to undertake encrypt and decrypt function. Many algorithms were implemented but it failed to provide protection against application-based attacks.

Das displayed a fresh algorithm for partial program authentication that runs in polynomial time and space, this algorithm can verify that a program pleases a specified sequential safety property. Their intuition is that by precisely demonstrating only those branches in a program for which the property-related behavior varies along the supports of the branch, an algorithm can be designed which is accurate in verification of the program. This is very helpful in solving the state-space explosion problem and can be applied to large programs. They have used the algorithm to provide the first verification of temporal safety properties for a program of the size of GCC.

During Covid-19 Outbreak, several incidents have been observed where cybercriminals acted as Officials from World Health Organization (WHO), Centre for Disease Control and Prevention (CDC). As per reports, 92% malware is transmitted through mails. Third party apps store almost 100% of discovered mobile malwares. On an average 70 records were stolen every second. It was found that it took around 7 months to detect a data leak within an enterprise. The average rate of data breach was found to be almost 5 million USD. Small businesses and enterprises were the victims of almost 50% of the data breaches. 54% of the data companies hold is Outdated. The largest data breach in the history of mankind is the 2013 Yahoo Data Breach where the data of almost half the population of world users were breached.

III. ALGORITHM

In cryptography algorithms are based on the process of encryption and decryption[18]. Encryption is changing the database into non-recordable script. Decryption shows the reverse process of encryption where it changes the cipher text to a normal text and decryption is the opposite operation of the technique of altering the normal text into illegible. There are basically two types of cryptography algorithms[19]:

A. Asymmetric Cryptography

Asymmetric cryptography is a cryptographic system in which public and private keys are used as a pair. Public key disseminated publicly and on the further side private key is known by real owner only.[17]

B. Symmetric Cryptography

In symmetric Cryptography the key used for encryption is similar to the key used in decryption. Thus the key distribution has to be made prior to the transmission of information. [16] The key plays a crucial part in symmetric cryptography since their security straightly counts on the nature of key[15] i.e. the key length and other factors.

There are multiple types symmetric cryptography which are widely used in the industry [14]. They are-

- 1) Data Encryption Standard (DES)
- 2) Triple Data Encryption Standard (3DES)
- 3) Blowfish
- 4) Advanced Encryption Standard (AES)

Each of the above mentioned algorithms uses different approaches for encryption purposes in a secured system however the methods used by DES and 3DES are mostly same. Data Encryption Standard (DES) practices a 56 bits to make the key secure whereas Triple Data Encryption Standard (3DES) uses 168 bits to make the key. The main difference is of size in both the algorithms, but the functioning of both the algorithms is more or less same [13]. But for our security system we will be using Advanced Encryption Standard (AES).

Advanced Encryption Standard (AES) whose original name is Rijndael, developed by the US National Institute of Standards and Technology (NIST) in early 2000s [12]. AES is the latest of the 4 present algorithms accepted for federal use in USA. AES is a symmetric encryption algorithm which is processing data in block size of 128-bits. AES is symmetric algo as the identical key is used for encryption as well as for the reverse transformation, decryption. The only secret necessary to keep for security is the key [11].

Features of AES are that in the contrast of DES algorithm [10] it works on SP network instead of a Feistel Cipher. AES can automatically expand keys as the number of rounds increase in successive trials. In AES the operations are performed [12] on byte data but not bit data, hence it treats the 128-bit key size as 16 byte during the procedure of encryption.

IV. METHODOLOGY

AES algorithm is one of the most complex algorithms of the recent times and takes a really long time to be broken. The complexity of this AES algorithm is hidden in its complex working [9]. AES algorithm follows the given to convert our Plain Text to Cipher Text.

A. Transformation Step

The processing steps are known as Transformation steps in which the Plaintext is changed into an array before proceeding further with the steps.

B. Substitution Step-

In this step each and every byte in the array is swapped with its sub byte.

For Example-

Y12 is replaced with Z12, where $Z12 = S(Y12) =$ Sub Byte of Y12, Z12 = A Array Byte

S = Sub Byte

C. Row-shifting Step-

The initial row remains the same in this step but the second row is moved from Right to Left single step at a time. These number of rounds keeps on increasing by one for every next row.

D. Column Mixing Step

In the following step the columns are selected one by one and each column is multiplied by a polynomial P.

E. Round-Key Addition Step

In the final step a round key is added in each byte of an array. A XOR gate is used for the purpose of adding of round key in the array.

Y, Z = Array Byte R = Round Key

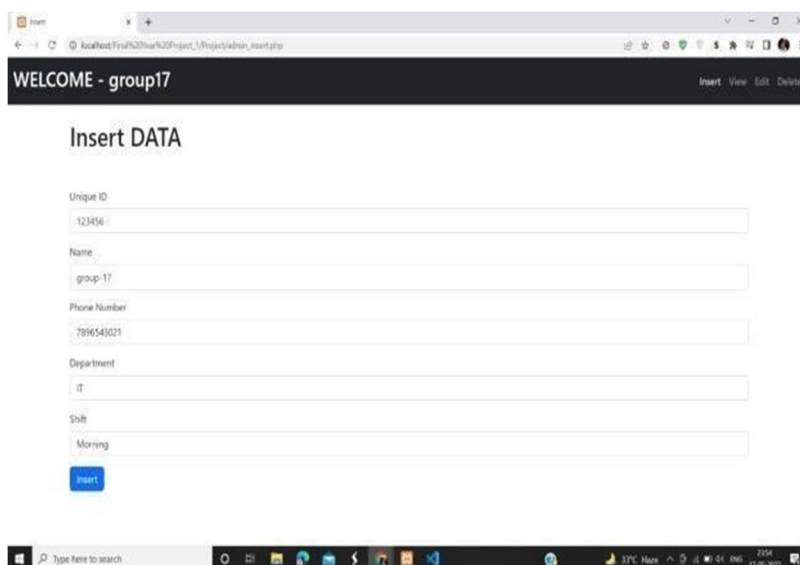

In the above process we can convert the Plain text into Cypher Text (encryption process). To convert the Cypher Text into Plain Text (decryption process) we have to reverse the same process and we will acquire the Plain Text.

V. RESULT

As a result, we have developed a system that is somewhat capable of encrypting the data within the database so that it can be stored in the encrypted form and when retrieved by an authorized personal it shows the decrypted form.

Below are some screenshots attached to show how the system works,

1) The main interface of the system from where a user can enter all the details to be entered.

VI. CONCLUSION

In this paper, we checked several cryptographic techniques and it is their components on which the whole method of cryptography works. Although, many difficulties arise in carrying out different cryptographic algorithms but there is always a technique that overpowers the concerns of threats. In our research paper we even conversed about diverse areas and sub techniques of cryptography. But although how hard we may try there's always a scope of error and threat. The systems, techniques and algorithms are getting advanced no doubt but we have to keep in mind that malicious persons are also using advanced techniques to steal the information by every fair or foul means. While enabling Transparent data Protection, it is a prudent idea that you should immediately backup the private key associated with the certificate and the certificate. If our certificate somehow gets inaccessible then you must attach the database on a different server, you must have backups of both: the certificate and the private key or else you will not be able to access the database. Deploying and integrating this system to its maximum potential requires massive funding and research.
