**Abstract:** Facial emotion recognition (FER) has become an important topic in the fields of computer vision and artificial intelligence due to its great academic and commercial potential. Although FER can be performed using multiple sensors, this review focuses on studies using facial images exclusively, since visual expressions are one of the main channels of information in human communication. Automatic emotion recognition based on facial expressions is an interesting research area that has been applied and applied in various fields such as safety, health and human-computer interface. Researchers in this field are interested in developing techniques to interpret, encode facial expressions and extract these features for better prediction by computer. With the remarkable success of deep learning, different types of architectures of this technique are exploited to achieve better performance. The purpose of this paper is to conduct a study of recent work on automatic facial emotion recognition (FER) via deep learning. We highlight these contributions, the architectures and the databases used, and we show the progress achieved by comparing the proposed methods and the obtained results. The purpose of this paper is to serve and guide researchers by reviewing recent work and providing insights to improve the field.

**Keywords:** facial emotion recognition, deep neural networks, automatic recognition, database

## I. INTRODUCTION

Automatic emotion recognition is a large and important research area that addresses two different subjects, which are psychological human emotion recognition and artificial intelligence (AI). Facial emotions are important factors in human communication that help us understand the intentions of others.

In general, people infer the emotional states of other people, such as joy, sadness, and anger, using facial expressions and vocal tone. The emotional state of humans can obtain from verbal and non-verbal information captured by the various sensors, for example from facial changes, tone of voice and physiological signals.

In 1967, Mehrabian [4] showed that 55% of emotional information were visual, 38% vocal and 7% verbal. Face changes during a communication are the first signs that transmit the emotional state, which is why most researchers are very interested by this modality.

In this paper, we provide a review of recent advances in sensing emotions by recognizing facial expressions using different deep learning architectures. We present recent results with an interpretation of the problems and contributions. It is organized as follows: in section two, we introduce some available public databases, section three; we present a recent state of the art on the FER using deep learning and we end in section four and five with a discussion and comparisons then a general conclusion with the future works.

## II. LITERATURE REVIEW

For automatic FER systems, various types of conventional approaches have been studied. The commonality of these approaches is detecting the face region and extracting geometric features, appearance features, or a hybrid of geometric and appearance features on the target face. For the geometric features, the relationship between facial components is used to construct a feature vector for training

Ghimire and Lee used two types of geometric features based on the position and angle of 52 facial landmark points. First, the angle and Euclidean distance between each pair of landmarks within a frame are calculated, and second, the distance and angles are subtracted from the corresponding distance and angles in the first frame of the video sequence. For the classifier, two methods are presented, either using multi-class AdaBoost with dynamic time warping, or using a SVM on the boosted feature vectors.

The appearance features are usually extracted from the global face region or different face regions containing different types of information.

Happy et al. utilized a local binary pattern (LBP) histogram of different block sizes from a global face region as the feature vectors, and classified various facial expressions using a principal component analysis (PCA). Although this method is implemented in real time, the recognition accuracy tends to be degraded because it cannot reflect local variations of the facial components to the feature vector. Unlike a global-feature-based approach, different face regions have different levels of importance. For example, the eyes and mouth contain more information than the forehead and cheek.

Ghimire et al. extracted region-specific appearance features by dividing the entire face region into domain-specific local regions. Important local regions are determined using an incremental search approach, which results in a reduction of the feature dimensions and an improvement in the recognition accuracy. For hybrid features, some approaches have combined geometric and appearance features to complement the weaknesses of the two approaches and provide even better results in certain cases. In video sequences, many systems are used to measure the geometrical displacement of facial landmarks between the current frame and previous frame as temporal features, and extract appearance features for the spatial features. The main difference between FER for still images and for video sequences is that the landmarks in the latter are tracked frame-by-frame and the system generates new dynamic features through displacement between the previous and current frames. Similar classification algorithms are then used in the video sequences, as described in [Figure 1](#). To recognize micro-expression, high speed camera is used to capture video sequences of the face.

Figure 1. Procedure used in conventional FER approaches: From input images (a), face region and facial landmarks are detected (b), spatial and temporal features are extracted from the face components and landmarks (c), and the facial expression is determined based on one of facial categories using pre-trained pattern classifiers (face images are taken from CK+ dataset (d).

Polikovskiy et al. presented facial micro-expressions recognition in video sequences captured from 200 frames per second (fps) high speed camera. This study divides face regions into specific regions, and then 3D- Gradients orientation histogram is generated from the motion in each region for FER.

Apart from FER of 2D images, 3D and 4D (dynamic 3D) recordings are increasingly used in expression analysis research because of the problems presented in 2D images caused by inherent variations in pose and illumination. 3D facial expression recognition generally consists of feature extraction and classification. One thing to note in 3D is that dynamic and static system are very different because of the nature of data. Static systems extract feature from statistical models such as deformable model, active shape model, analysis of 2D representations, and distance-based features. In contrast, dynamic systems utilize 3D image sequences for analysis of facial expressions such as 3D motion-based features. For FER, 3D images also use the similar conventional classification algorithms. Although 3D-based FER showed higher performance than 2D-based FER, 3D and 4D-based FER also has certain problems such as a high computational cost owing to a high resolution and frame rate, as well as the amount of 3D information involved. Some researchers have tried to recognize facial emotions using infrared images instead of visible light spectrum (VIS) image because visible light (VIS) image is variable according to the status of illumination.

Zhao et al. used near-infrared (NIR) video sequences and LBP-TOP (Local binary patterns from three orthogonal planes) feature descriptors. This study uses component-based facial features to combine geometric and appearance information of face. For FER, a SVM and sparse representation classifiers are used.

Shen et al. used infrared thermal videos by extracting horizontal and vertical temperature difference from different facial sub-regions. For FER, the Adaboost algorithm with the weak classifiers of k-Nearest Neighbor is used.

Szwoch and Pieniążek recognized facial expression and emotion based only on depth channel from Microsoft Kinect sensor without using camera. This study uses local movements within the face area as the feature and recognized facial expressions using relations between particular emotions. Sujono and Gunawan used Kinect motion sensor to detect face region based on depth information and active appearance model (AAM) to track the detected face. The role of AAM is to adjust shape and texture model in a new face, when there is variation of shape and texture comparing to the training result. To recognize facial emotion, the change of key features in AAM and fuzzy logic based on prior knowledge derived from FACS are used. Wei et al. proposed FER using color and depth information by Kinect sensor together. This study extracts facial feature points vector by face tracking algorithm using captured sensor data and recognize six facial emotions by random forest algorithm.

Commonly, conventional approaches determine features and classifiers by experts. For feature extraction, many well-known handcrafted features, such as HoG, LBP, distance and angle relation between landmarks are used and the pre-trained classifiers, such as SVM, AdaBoost, and random forest, are also used for FER recognition based on the extracted features. Conventional approaches require relatively lower computing power and memory than deep learning-based approaches. Therefore, these approaches are still being studied for use in real-time embedded systems because of their low computational complexity and high degree of accuracy. However, feature extraction and the classifiers should be designed by the programmer and they cannot be jointly optimized to improve performance.

One of the success factors of deep learning is the training the neuron network with examples, several FER databases now available to researchers to accomplish this task, each one different from the others in terms of the number and size of images and videos, variations of the illumination, population and face pose. Some presented in Table.1 in which we will note its presence in the works cited in the following section.

### III. FACIAL EMOTION RECOGNITION USING DEEP LEARNING

Despite the notable success of traditional facial recognition methods through the extracted of handcrafted features, over the past decade researchers have directed to the deep learning approach due to its high automatic recognition capacity. In this context, we will present some recent studies in FER, which show proposed methods of deep learning in order to obtain better detection. Train and test on several static or sequential databases.

Mollahosseini et al. propose deep CNN for FER across several available databases. After extracting the facial landmark from the data, the images reduced to 48x 48 pixels. Then, they applied the augmentation data technique. The architecture used consist of two convolution-pooling layers, then add two inception styles modules, which contains convolutional layers size 1x1, 3x3 and 5x5. They present the ability to use technique the network-in-network, which allow increasing local performance due to the convolution layers applied locally, and this technique also make it possible to reduce the over-fitting problem.

Lopes et al. [24] Studied the impact of data pre-processing before the training the network in order to have a better emotion classification. Data augmentation, rotation correction, cropping, down sampling with 32x32 pixels and intensity normalisation are the steps that were applied before CNN, which consist of two convolution-pooling layers ending with two fully connected with 256 and 7 neurons. The best weight gained at the training stage are used at the test stage. This experience was evaluated in three accessible databases: CK+, JAFFE, BU-3DFE. Researchers show that combining all of these pre-processing steps is more effective than applying them separately.

These pre-processing techniques also implemented by Mohammad pour et al. They propose a novel CNN for detecting AUs of the face. For the network, they use two convolution layers, each followed by a max pooling and ending with two fully connected layers that indicate the numbers of AUs activated.

In 2018, for the disappearance or explosion gradient problem Cai et al. propose a novel architecture CNN with Sparse Batch normalization SBP. The property of this network is to use two convolution layers successive at the beginning, followed by max pooling then SBP, and to reduce the over-fitting problem, the dropout applied in the middle of three fully connected. For the facial occlusion problem Li et al. present a new method of CNN, firstly the data introduced into VGG Net network, then they apply the technique of CNN with attention mechanism ACNN. This architecture trained and tested in three large databases FED-RO, RAF-DB and Affect Net.

Detection of the essential parts of the face was proposed by Yolcu et al. They used three CNN with same architecture each one detect a part of the face such as eyebrow, eye and mouth. Before introducing the images into CNN, they go through the crop stage and the detection of key-point facial. The iconic face obtained combined with the raw image was introduced into second type of CNN to detect facial expression. Researchers show that this method offers better accuracy than the use raw images or iconize face alone (See Fig. 1.a).

In 2019, Agrawal et Mittal make a study of the influence variation of the CNN parameters on the recognition rate using FER2013 database. First, all the images are all defined at 64x64 pixels, and they make a variation in size and number of filters also the type of optimizer chosen (adam, SGD, adadelta) on a simple CNN, which contain two successive convolution layers, the second layer play the role the max pooling, then a soft max function for classification. According to these studies, researchers create two novel models of CNN achieve average 65.23% and 65.77% of accuracy, the particularity of these models is that they do not contain fully connected layers dropout, and the same filter size remains in the network.

Deepak Jain et al. propose a novel deep CNN which contain two residual blocks, each one contain four-convolution layer. These model trains on JAFFE and CK+ databases after a pre-processing step, which allows cropping and normalizing the intensity of the images.

Kim et al. 31 studies variation facial expression during emotional state, they propose a spatio-temporal architecture with a combination between CNN and LSTM. At first time, CNN learn the spatial features of the facial expression in all the frames of the emotional state followed by an LSTM applied to preserve the whole sequence of these spatial features. Also Yu et al. Present a novel architecture called Spatio-Temporal Convolutional with Nested LSTM (STC-NLSTM), this architecture based on three deep learning sub network such as: 3DCNN for extraction spatio-temporal features followed by temporal T-LSTM to preserve the temporal dynamic, then the convolutional C-LSTM for modelled the multi-level features.

Deep convolutional Bi LSTM architecture was proposed by Liang et al. they create two DCNN, one of which is designated for spatial features and the other for extracting temporal features in facial expression sequences, these features fused at level on a vector with 256 dimensions, and for the classification into one of the six basic emotions, researchers used Bi LSTM network. For the pre-processing stage, they used the Multitask cascade convolutional network for detecting the face, then applied the technique of data augmentation to broaden database (See Fig.1.b).

All of the researchers cited previously classifying the basic emotions: happiness, disgust, surprise, anger, fear, sadness. and neutral, Fig 3. Present some different architecture proposed by the researchers who mentioned above

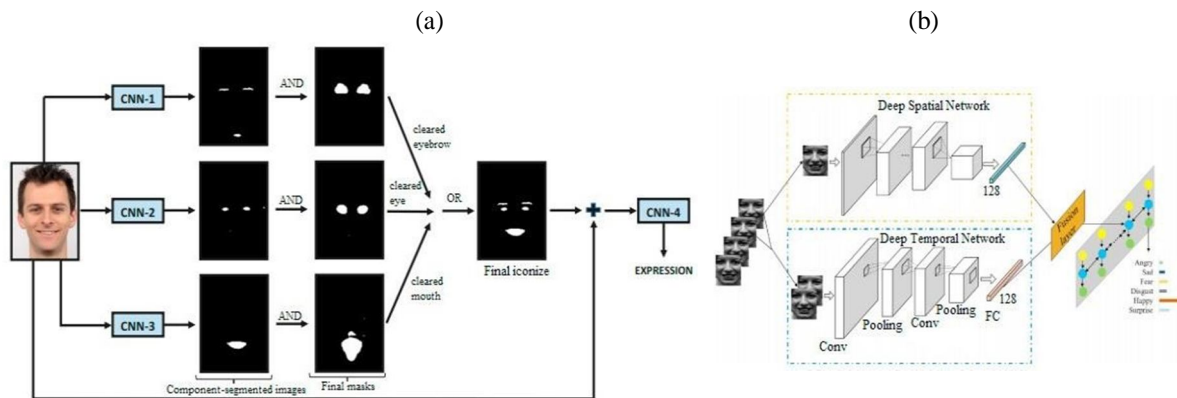

Fig. 1. Different deep learning methods proposed by Yoclu et al. and (b). Liang et al.

#### IV. DISCUSSION AND COMPARISON

In this paper, we clearly noted the significant interest of researchers in FER via deep learning over recent years. The automatic FER task goes through different steps like: data processing, proposed model architecture and finally emotion recognition.

The preprocessing is an important step, which was present in all the papers cited in this review, that consist several techniques such as resized and cropped images to reduce the time of training, normalization spatial and intensity pixels and the data augmentation to increase the diversity of the images and eliminate the over-fitting problem. All these techniques are well presented by Lopes et al.

Several methods and contributions presented in this review was achieved high accuracy. Mollahosseini et al. showed the important performance by adding inception layers in the networks. Mohammad pour et al. 25 prefer to extract AU from the face than the classification directly the emotions, Li et al. is interested in the study the problem of occlusion images, also for to get network deeper, Deepak et al. propose adding the residual blocks. Yolcu et al. 28 shows the advantage of adding the iconized face in the input of the network, enhance compared with the training just with the raw images. For Agrawal et Mittal. offers two new CNN architecture after an in-depth study the impact of CNN parameters on the recognition rate. Most of these methods presented competitive results over than 90%.

For extraction the spatio-temporal features researchers proposed different structures of deep learning such as a combination of CNN-LSTM, 3DCNN, and a Deep CNN. According to the results obtained, the methods proposed by Yu et al. and Liang et al. 33 achieve better precision compared to the method used by Kim et al. 31. With a rate higher than 99%.

Researchers achieve high precision in FER by applying CNN networks with spatial data and for sequential data, researchers used the combination between CNN-RNN especially LSTM network, this indicate that CNN is the network basic of deep learning for FER. For the CNN parameters, the Soft max function and Adam optimization algorithm are the most used by researchers. We also note in order to test the effectiveness of the proposed neural network architecture, researchers trained and tested their model in several databases, and we clearly see that the recognition rate varies from one database to another with the same DL model (See Table.1). Table1 summarize all the articles cited above, lists the architecture, the database and the recognition rate.

Table 1 Comparison between presented works.

Authors	databases	The architecture used	Recognition rate
Mollahosseini et al.	MultiPie10, MMII1, DISFA34, FERA12,	CNN	94.7%, 77.9%, 55%
	SFEW13, CK+14, FER201315		76.7%, 47.7%,
			93.2%, 61.1%
Lopes et al.	CK+14, JAFFE16, BU-3DFE17	CNN	96.76% for CK+
Mohammad pour et al.	CK+14	CNN	97.01%
Cai et al.	JAFFE16, CK+14	SBN-CNN	95.24%, 96.87%
Li et al.	RAF-DB21, AffectNet20	ACNN	80.54%, 54.84%
Yolcu et al.	RafD22	CNN	94.44%
Agrawal et Mittal.	FER201315	CNN	65%
Deepak jain et al.	JAFFE16, CK+14	CNN	95.23%, 93.24%
Kim et al.	MMII1, CASME II 18	CNN-LSTM	78.61%, 60.98%
Yu et al	CK+14, Oulu-CASIA19, MMII1,	STCNN LSTM	99.8%, 93.45%,
	BP4D35		84.53%
Liang et al.	CK+14, Oulu-CASIA19, MMII1	UCF101	99.07%, 91.07%
		IJCB13101	80.71%

### V. CONCLUSION AND FUTURE WORK

This paper briefly reviews the FER method, allowing us to understand the recent developments in the field. As we describe, these methods can be divided into two main streams: Traditional FER methods consist of three steps, namely face and facial component detection, feature extraction, and expression classification. We describe different architectures of CNNs and CNN-LSTMs recently proposed by different researchers, and propose several different databases containing spontaneous images collected from the real world and others formed in the laboratory in order to accurately detect human emotions. We also present a discussion showing the high ratios obtained by the researchers, which highlights that today's machines will be more capable of interpreting emotions, implying that human-computer interactions are becoming more and more natural. FERs are one of the most important ways to provide information about emotional states, but they have always been limited by learning only the six basic and neutral emotions. It clashes with what exists in everyday life, which has more complex emotions. This will push researchers to build larger databases and create powerful deep learning architectures to identify all primary and secondary emotions in future work. Furthermore, emotion recognition today has evolved from single-modal analysis to multi-modality in complex systems.
