**Abstract:** FIR (First Information Report) datamanagement is a critical task for law enforcement agencies to maintain law and order. Traditional FIR data management system often plagued by issues of data tampering, unauthorized access, and lack of transparency. In order to overcome this blockchain technology has been implemented which offers a decentralized, secure, and transparent solution to these problems. Storing FIR data on the blockchain can provide several advantages, including increased security, transparency, and immutability. Blockchain technology is a decentralized system that is resistant to modification, making it ideal for storing sensitive data such as FIR data. This system proposes a blockchain-based FIR data management system that utilizes smart contracts to automate the process of registering and accessing FIR data. The immutability of blockchain records can increase the reliability and trustworthiness of FIR data, while the decentralization of the blockchain ensures that there is no single point of failure. The user interface provides a graphical user interface for authorized users to interact with the system, Crime Investigators can view the data from database using their authentication credentials. Thereports, which are prepared by witnesses and police officers, are accessible to the investigator (admin).Investigators have the authority to edit data (i.e., update, remove, and so on), and this data aids investigators in speeding up their investigations and identifying offenders more quickly. The evidences are secured using Block chain technology with SHA algorithm to create the hash values for each record. Secure cryptography functions to encrypt FIR information before storing on server has been implemented. The blockchain technology has the potential to revolutionize FIR data storage and improve the efficiency and effectiveness of law enforcement agencies.

## I. INTRODUCTION

FIR data management is an essential task for law enforcement agencies worldwide. FIR is the first official documents recorded by police when a crime is reported. These documents contain crucial information such as the victim's name, the accused name, the type of crime committed, the location of the crime, and other relevant details. FIR data is critical for investigations, evidence gathering, and judicial proceedings. Blockchain technology offers a decentralized, secure, and transparent solution to store the FIR data. A blockchain collects information together in groups, known as blocks. Each block hold sets of information that are linked to the previously filled block, forming a chain of data known as the blockchain.

## II. EXISTING SYSTEM

The existing methods store this FIR data in manual filing and the e-copies are stored in centralized criminal record database. This does not ensure data security up to the mark. It could be tampered by third-party or even possible to be changed by the police officers for their own benefit.

Disadvantage

Compromised FIR information may ultimately result in favor of the criminal and a disgrace to our justice system.

## III. PROPOSED SYSTEM

Blockchain technology offers a secure, and transparent solution to these problems. Blockchain is a distributed ledger technology that allows data to be stored and managed securely and transparently without the need for a central authority. Blockchain technology offers several advantages over traditional data management systems, such as immutability, transparency, and security. The sensitive and crucial information contained in the FIR is stored in distributed database and is also encrypted making it not useful for the intruder even a database is compromised.

Advantages

Storing FIR data using blockchain makes it very difficult to alter or delete the record without leaving a trace, because of this we can prevent data tampering and maintaining distributed database prevents data loss and also making it accessible from anywhere.

**A. Blockchain**

Blockchain builds on the idea of P2P networks and provides a universal data set that every actor can trust, even though they might not know or trust each other. It provides a shared and trusted ledger of transactions, where immutable and encrypted copies of information are stored on every node in the network. Economic incentives in the form of native network tokens are applied to make the network fault tolerant, and attack and collusion resistant. All network participants have equal access to the same data in real-time. Transactions running over the network are transparent to all actors and can be traced back to their origin.

**B. Storage Mechanism**

A blockchain is a digital concept to store data. These blocks are chained together, and this makes their data immutable. When a block of data is chained to the other blocks, its data can never be changed again. It will be publicly available to anyone who wants to see it ever again, in exactly the way it was once added to the blockchain. The most adopted secure algorithms associated with the blockchain technology are (SHA-1, SHA-2, and SHA-256) encryption because of their unique quality of hash function that creates unique outputs when given different inputs. The hash function here is a unique key created to identify a transaction that at the same time identifies an individual in the chain.

**C. Hashing**

As the data blocks stored has distinct generated hash value mapped to them, these hashes are then linked in an order of creation. These hash values are needed in the processes of retrieving the data blocks.

Here hashing is done by SHA-256 as it is considered as more secure algorithm than MD because this hash functions that do not have collusion problems and deemed secure otherwise, at least as yet.

- 1) **Blockchain headers:** Previous hash which locates the previous block's hash, Transaction details, Nonce which is an arbitrary number given by cryptography to differentiate the block's hash address.
- 2) **Hash Address:** Preceding hash, transaction details, and nonce are transmitted through a hashing algorithm. This gives an output containing a 256-bit, 64 character length value, which is called the unique 'hash address.' Consequently, it is referred to as the hash of the block.
- 3) **Mining:** In Blockchain technology, the process of adding transactional details to the present digital/public ledger is called 'mining'. Mining involves generating the hash of a block transaction, which is tough to forge, thereby ensuring the safety of the entire Blockchain without needing a central system.

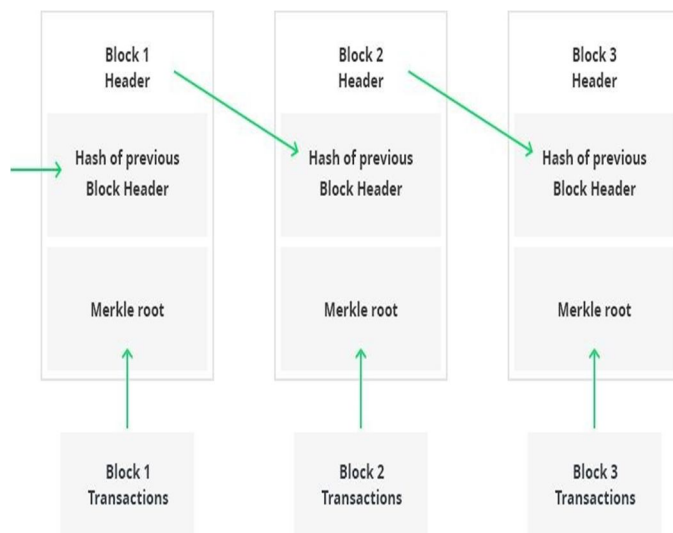

Fig.1 Data Storage

**D. System Architecture**

System architecture is the conceptual model that defines the structure, behavior, and more views of a system. An architecture description is a formal description and representation of a system, organized in a way that supports reasoning about the structures and behaviors of the system.

Fig.2 Architectural Diagram

**E. Module Description Demystifying Userroles**

This system will incorporate three roles of user asin admin, officer who will the writer who files the FIR in police station, the court end whom have access to retrieve the stored FIR data. And also these ends need tobe access the data in a secure manner.

**1) Entering Data Into The System**

FIR data collection process is done by officer whohas authority to add FIR information. Each officer should have unique login factors. The authenticated officer can add FIR information regarding crime. Officer add the newFIR which contains the information such as station number, user name, FIR number, date, victim, witness, accused and FIR document.

**2) Chaining Hashes**

The uniquely generated hash of each data blocksusing SHA-256 hashing algorithm is chained ensuring thetransaction cannot be modified or tampered with. The modification will not be possible if the hash of the particular data block, to retrieve the hash value in the chain there is a need for the previous and the following hash value of blocks in the formed chain.

**3) Data Retrieval**

The stored FIR data needs to be retrieved by authorized personnel that is the court, court admin can login and search FIR data regarding inquiry process. It ensures the integrity and confidentiality of FIR data.

**4) Overall Operation**

A Block containing information about currenttransactions. Each data generates a hash. A hash is a string of numbers and letters. Transactions are entered in the order in which they occurred. The hash depends not only on the transaction but the previous transaction'shash. Even a small change in a transaction creates a completely new hash. The nodes check to make sure a transaction has not been changed by inspecting the hash.If a transaction is approved by a majority of the nodes then it is written into a block. Each block refers to the previous block and together make the Blockchain. A Blockchain is effective as it is spread over many computers, each of which has a copy of the Blockchain.

**IV. IMPLEMENTATION**

For the implementation, appropriate selection oflanguage is chosen and the design is transformed into working system. Aim of the phase is to translate the design intoa best possible solution in a suitable programming language. This chapter covers the implementation aspects of the project, giving details of the programminglanguage and development environment used. It also gives an overview of the core modules of the project withtheir step by step flow.

The implementation stage requires the following tasks.

- 1) Careful planning.
- 2) Investigation of the system and constraints.
- 3) Design of methods to achieve the changeover.
- 4) Evaluation of the changeover method.
- 5) Correct decisions regarding selection of the platform

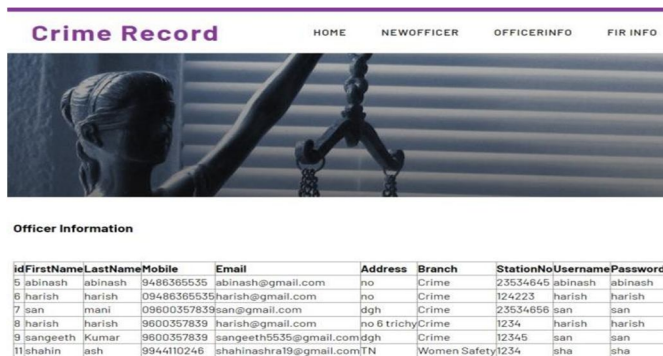

The front-end is developed using ASP.NET. With ASP.NET(Active Server Pages) and code-behind, the code and HTML can be isolated. It Utilize code to call local Windows APIs, use pre-constructed COM parts, and influence existing ActiveX controls to flawlessly coordinate existing applications and segments.

The backend uses SQL server for storing data in multiple instances. SQL Server scales from a portable tablet to symmetric multiprocessor frameworks.

### V. EXPERIMENTAL RESULTS

All field entries must work properly. Pages must be activated from the identified link. The entry screen, messages and responses must not be delayed. Features to be tested:

- 1) Verify that the entries are of the correct format.
- 2) No duplicate entries should be allowed.
- 3) Modification in any database entry should be verified for integrity with other database instances for trustworthiness.
- 5) The uploaded relevant documents, photos and entered details should be stored properly.
- 6) No unauthorized access should be permitted.
- 7) All Admin features must work properly.
- 8) The court module must be able to retrieve the correct document using case ID.
- 9) The retrieved details must be properly decrypted for readability.

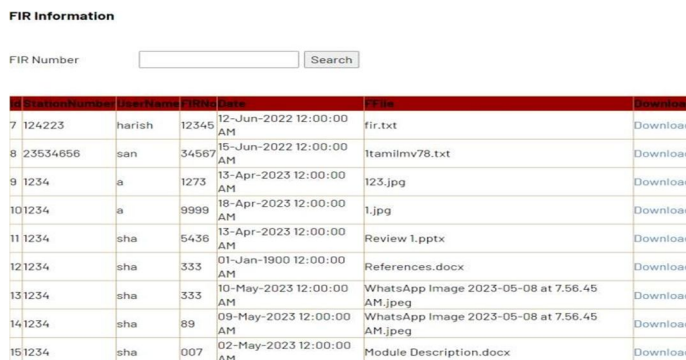

The screenshot shows a web application titled "Crime Record" with a navigation menu including HOME, NEW OFFICER, OFFICER INFO, and FIR INFO. Below the menu is a header image of a scale of justice. Underneath is a section titled "Officer Information" containing a table with columns: id, FirstName, LastName, Mobile, Email, Address, Branch, StationNo, Username, Password.

id	FirstName	LastName	Mobile	Email	Address	Branch	StationNo	Username	Password

## VI. CONCLUSION

The proposed blockchain-based FIR data management system offers several advantages over traditional FIR data management systems. It provides a secure, decentralized, and transparent solution to the problems of data tampering, unauthorized access, and lack of transparency. The system ensures data integrity, confidentiality, and authenticity while providing transparency and accountability to all stakeholders. This can improve the efficiency and effectiveness of FIR data management, thereby helping law enforcement agencies maintain law and order.
