Food Image Recognition and Calorie Prediction

Akarsh V¹, Aswathy Santhosh C², Jessil Thomas³, Rekha M S⁴, Steffi Thomas⁵

Department of Computer Engineering, Visvesvaraya Technological University

Abstract: This paper pivot on food classification also with boosting the task accuracy and also productivity through the usage of deep learning algorithms food classification is a major component in applications such as nutritional knowledge and restaurant menu analysis and recognizing food items from photographs is a big difficulty the cony-net and resnet152v2 were set to take on this task this study focuses on the potential of transfer learning to simplify food categorization procedures with algorithm selection playing an important part in reaching high accuracy rates as the amount of food-related applications grows the result of this can act as the selection of transfer-learning algorithms to enhance food recognition and classification systems allowing for breakthroughs in fields such as nutritional analysis and food recommendation systems in this food categorization.

Keywords: Food Image Recognition, task, accuracy, nutritional, analysis, Convolutional Neural Network, Deep Learning Approach, Image Recognition.

I. INTRODUCTION

Food has existed as a necessity for human existence since the beginning of time and is currently gaining more attention than it did in the past. Currently, the main technique used in food supply is to precisely identify and choose the right food items for human visual inspection. This procedure is costly and time-consuming. Therefore, it is essential to have a food image diagnosis system that can automatically classify approved food items. Major advancements in surveillance, medical imaging, detecting, and observing have been made possible by recent forming in processing and identification.

While data mining and machine learning tactics have been successfully applied to automatically classify food photographs, most existing systems classify diets, and datasets often contain entire meals. A limited number of specially produced exist for pictures of food items, and much scrutiny has not been done on multi-class. The different food groups, each with distinct traits and commonalities, are hard for traditional identification techniques to take into consideration. There are advantages and disadvantages to employing different strategies to address this problem, such as creating complex features for enhanced representation even when complex and situation-specific design issues arise. When making decisions, the suggested method gives information the upper hand over intricate representations.

II. METHODOLOGY

It will provide a detailed description of the methods utilized to finish and operate this project successfully. Many methodologies or discoveries from this subject are mostly published in journals for others to use and enhance in future research. The approach is used to attain the project's purpose of producing a faultless output. The technique used to analyse this project is based on the System Development Life Cycle (SDLC), which consists of three primary steps: planning, implementation, and analysis.

A. Planning

Planning needs to be done correctly in order to identify every piece of information and necessity, including software and hardware. Data gathering and the hardware and software requirements are the two primary components of the planning process.

B. Data collection

Make sure the data you are gathering has enough features supplied aiming for your learning model to be appropriately trained. Check you include enough rows since, generally speaking, the more data you have, the better. The initial data which was stack up from web sources is still available in its unprocessed form as sentences, numbers, and qualitative phrases. The unprocessed data contains inconsistencies, omissions, and mistakes. After carefully examining the filled surveys, modifications are necessary. The proceeding of primary data requires the following processes. It is necessary to aggregate a sizable amount of raw data from field surveys so that it finds the details about individual replies that are comparable. Data preparation is one way to turn the raw data into a clean data collection. Stated differently, if data is acquired in unprocessed form from several sources; analysis is not appropriate. A few steps are taken to convert the data into a small, clean data collection.

This way is used before doing an iterative analysis. The set of procedures is called data preparation. Included are data reduction, data cleansing, data integration, and data transformation. Preprocessing of data is necessary since unformatted real-world data does exist. The predominance of data in the real world is inaccurate or missing: Missing data can have a quota of sources, such as erratic data gathering, mistakes in Data preparation is one way to turn the raw data into a clean data collection. Stated otherwise, if data is acquired in unprocessed form from several sources, it is inappropriate for examination. A few steps are taken in aiming to convert the data into a small, clean data collection. This plan is used before doing an iterative analysis. The set of procedures is called data preparation. Included are data reduction, data cleansing, data integration, and data transformation. Preprocessing of data is necessary since unformatted real-world data does exist.

III.LITERATURE REVIEW

It is very important to people in the modern society, especially the elderly. Generally speaking, food consumption is determined using a scale. Despite this, it is laborious because each food item demands to be measured separately before and after consumption. Direct measurement of amount of food consumed on the meal tray is done using a short-range depth camera, which increases measuring ease of use.

To attain the previously indicated goal, two main problems emerge. The impact of the tray's content comes first. The other pixel in the depth image is the one that has no depth values. The estimate is first converted to weight using the specific gravity function, after which the volume is computed. The weight is then converted to calories using the food calorie computation. We can use linear, quadratic or cubic functions to approximate the specific gravity function of any meal. The lowest average inaccuracy of food intake weight in the experimental investigation is 5.6 grams. It is approximately 7.5%. The findings show the victory of the suggested approach in estimating the weight of food consumed. We suggest 1 3 "Calorie Captor Glass," a HoloLens-based image-based food calorie estimate device. To approximate the specific gravity function of any meal, one can utilize cubic, quadratic, or linear functions.

In the experimental inquiry, the food intake weight with the lowest average inaccuracy is 5.6 grams. That comes to about 7.5%. The results show how well the recommended method works for finding the weight of food consumed. We recommend 1 3 "Calorie Captor Glass," an image-based meal calorie estimation tool based on HoloLens technology. We leverage HoloLens's 3D environment recognition capability to estimate meal sizes accurately, allowing for precise calorie and quantity estimates. Using the combination of CNN-based food picture segmentation and predicted 2D meal sizes and meal-dependent quadratic curves between meal size and calories, we estimate the calorie intake of 46 different varieties of meals.

HoloLens displays the anticipated meal categories and calories over the augmented reality area, inviting us to try this unique dining experience. For medical needs, a food nutrition and energy intake identification system will be suggested. In summation to nutritional information tables, this routine is based on food picture processing and shape identification. The device uses a unique road to take pictures of the meal both before consumption and also after consumption so that we can work out how many calories and nutrients the chosen food contains.

Our approach offers a novel tool for determining the food intake that has potential applications and efficacy in the treatment of obesity. People these days have demonstrated a strong desire to lose weight by tracking the number of calories they eat. The assessment of nutrition and calories is used to track body fat. The calorie values in this dietary management system are determined using features extraction, segmentation, and classification. Next, using the food area volume and nutrition measure based on the mass value, the calorie value is calculated. The nutritional evaluation provides an effective method for a person's food consumption by figuring out the calories in each meal item. Here, the food items are segmented using the FCM method, and the segmented food items are then classified using a Sphere Shaped SVM classifier. The food products are automatically identified, and their calorie value is subsequently determined using this procedure. With a 95% accuracy rate, the suggested approach achieves superior categorization.

This research proposes a mechanism for medical applications to recognize dietary nutrition and energy consumption. Additionally for nutritional information tables, this medium is based on food picture processing and shape identification. Numerous studies conducted recently have indicated that serve patients who are obese or overweight may help more from using technology, such as smartphones. The device uses a unique method to take pictures of the meal both before and after consumption in order to calculate how many calories and nutrients the chosen food contains. Our approach offers a novel mechanism for judging food intake that has potential applications and efficacy in the care of obesity.

IV. SYSTEM ARCHITECTURE

The relationships between various components might be displayed using a system architecture diagram. They are again and again designed for hardware and software-based systems and the figures display how all these parts interact. System architectures may be split into three parts they are mixed (partially dispersed and partially integrated), integrated, and distributed. It is demonstrated that an architecture's type is determined by its interfaces. More interfaces are present in integrated systems and these bonds are also not well defined. The planning and design phase, operational analysis phase, requirements analysis phase, function analysis phase, and physical synthesis phase are the five processes that should make up the creation of a systems architecture.

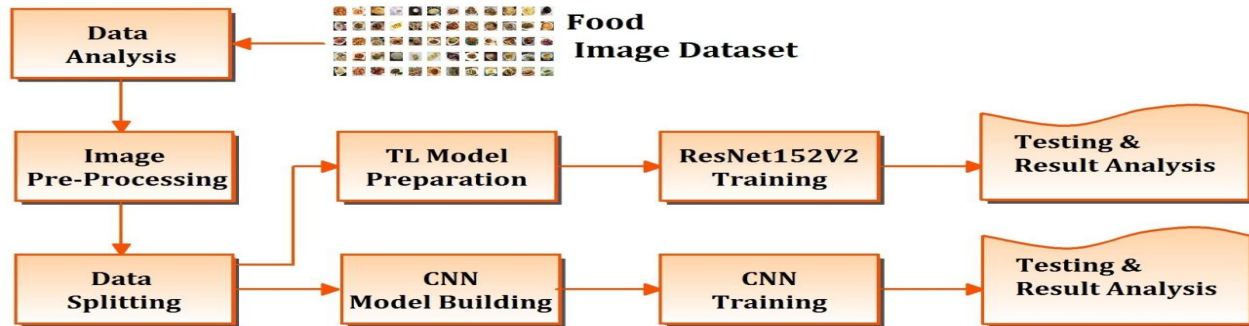

Fig 4.1 System Architecture

V. ALGORITHM

A. Convolution Neural Network (CNN)

CNN is organized into two sections. The feature is extracted by the feature extraction layer by connecting each neuron's input to the regional ready fields of the preceding layer. The positional link between local features and other features will be shown when they have been retrieved. The other is the feature map layer, which is utilized by all network computing layers. Each feature map may be an idea of a machine of the same weight. for each neuron. The convolutional activation function of the system is the sigmoid function, which can be used for the feature plan structure. The feature map's difference shifts as a result. More over because neurons in the same mapping plane share weight of the network which has fewer free parameters.

Fig 5.1 Convolution Neural Network

B. ResNet152V2

A deep learning version called ResNet152V2 is intended for object identification and picture categorization. This is an update to the Res-Net framework, which was initially made ready to use in 2015. The knack of the Res-Net version to comprehend deep photos with little parameters is well known. With 152 convolutional layers, ResNet152V2 was initially trained on the ImageNet dataset, which had over 14 million images and 1,000 classifiers. ResNet152V2 is able to accumulate sophisticated functionalities appropriate for photo popularity tasks thanks to this first training. A highly strong model, ResNet152V2, has proven to function well in the present day for object identification and photo categorizing. It is frequently employed as the beginning point for switch learning, in which the model that was previously skilled is fine-tuned.

VI. RESULT AND DISCUSSION

A result is the outcome of actions or occurrences, represented subjectively or quantitatively. Performance analysis is an operational study that establishes a fundamental quantitative link between performance quantities.

Metrics	Definition
Precision	Accuracy is defined as the total ratio, the true and false positive values of successful assertions, and both.
Recall	Recall is defined as the ratio of all true negatives and false negatives to genuine positives.
F1 Score	To quantify this recall and accuracy, the weighted harmonic average, or F1, is used. The estimated power of the model rises as the F1 score gets closer to 1.0.
Support	The level of instances of a class that are present in the dataset is known as the number of supports. It doesn't differentiate between various types; it only aids in the performance assessment process.

VII. CONCLUSIONS

We offer an intelligent food recognition and calorie prediction system that predicts the level of calories in a given food image. The e-system automatically estimates the calories in the food simply by taking a photo of the food from above using a pre-registered Reference Article. Also, a bunch of data augmentation and segmentation must be done, and pure pixel values are not needed in CNN, because it learns the general pattern needed to detect and recognize new images by itself. So, using CNN model the accuracy is relatively a lot of other normal models. This gives almost 70% accuracy. An image of food as input to the system, it quickly recognizes the food/products shown in the image and its caloric value as output displayed in the picture together with the output's calorie value.
