Multifunctional Control for PV Integrated Battery Energy Storage System with Enhanced Power Quality

B. Murali Mohan¹, S. Gurucharan², V. Achyuth Reddy³, P. Balaji⁴, B. Karthik Kuma⁵

^{1,2,3,4} *Electrical and Electronics Engineering Department, Annamacharya Institute of Technology & sciences, Rajampet, Andhra Pradesh, India*

Abstract: *This modest paper presents a study on the energy quality produced by a multifunction system consisting of a Photovoltaic (PV) power source connected to a battery. A three-level inverter was used in the system studied for the purpose of improving the quality of energy injected into the grid and decreasing the Total Harmonic Distortion (THD). A Maximum Power Point Tracking (MPPT) algorithm based on a Fuzzy Logic Controller (FLC) is used for the purpose of ensuring optimal production of photovoltaic energy. In addition, another FLC controller is used to ensure DC bus stabilization. The considered system was implemented in the Matlab/Simpower environment. The results show the effectiveness of the proposed inverter at three levels in improving the quality of energy injected from the system into the grid.*

I. INTRODUCTION

Global interest in clean and renewable energy sources (RESs) has been growing exponentially. Solar energy is gaining importance as a renewable source due to advantages such as low maintenance, no noise, no fuel cost, and low wear and tear due to the absence of moving parts [1– 6]. The energy conversion efficiency of a PV array is low and varies with solar intensity and operating temperature [7]. The tracking control of the maximum power point is a key and complex issue. Therefore, to achieve the maximum efficiency possible, Maximum Power Point Tracking (MPPT) control is critical to the success of PV systems. To mitigate the problems involved, various tracking control strategies have been discussed in past literature with a view to obtaining maximum energy conversion efficiency of the PV array for all operation conditions, such as perturb and observe [3, 8] and incremental conductance [8–11]. These strategies have disadvantages such as difficulty, high cost, instability and complexity. To overcome these disadvantages, several researchers have used artificial intelligence approaches such as Fuzzy Logic Controller (FLC) [6, 12–17] and Artificial Neural Network (ANN) [18–22] to obtain maximum energy conversion efficiency. This study discusses the FLC method to deliver MPPT for a PV system. Fuzzy logic is robust and relatively simple to design, since it does not require information regarding the exact model or load level. Another element that plays a very important role in solar generation power systems is battery storage [2, 17].

Batteries are used to store superfluous energy derived from solar irradiance on sunny days and for release on cloudy days or at night. Battery technology has made considerable advances, the rechargeable battery has been upgraded from a lead acid battery to a nickel-based battery and from a nickel-based battery to a lithium-ion (Li-ion) battery. Nowadays, Li-ion batteries are widely adopted in portable electronic devices, such as smart phones, digital cameras and laptop computers. Lithium-ion batteries enjoy higher energy density, higher terminal voltage and higher power density than other rechargeable batteries. This study integrated a PV system with a Li-ion battery charging system connected to the grid via a three-level neutral point clamp (NPC) inverter. Multilevel converters are considered to be the most suitable power converters in renewable energy applications, especially in developing high-power generators [6]. Multilevel converters present many advantages when compared with the standard two-level conventional converters, such as improved output voltage waveform, reduced harmonic content, increased power rating, and decreased stress across the switches. However, their main disadvantage is the balancing of the capacitor voltages in the DC link [3].

II. MODELLING OF THE PV-BATTERY SYSTEM

The proposed grid-connected PV-battery system is shown in Fig. 1. The PV array is connected to the DC bus via a boost converter controlled by a MPPT algorithm to extract the maximum power. The DC bus is then connected to the AC bus through the NPC three-level inverter.

The battery is connected to the DC link through a DC-DC bidirectional converter and contributes to the regulation of the DC link voltage and to power balance the supply and demand of power. A small L- filter is connected with the inverter output to eliminate high frequency harmonics.

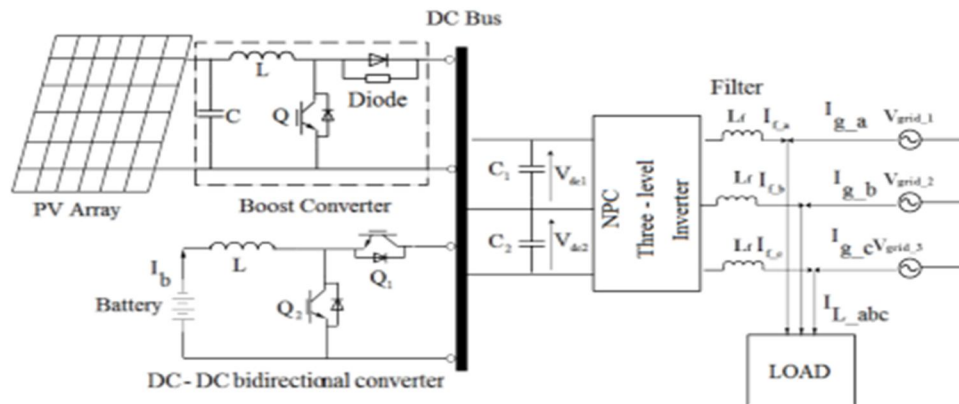

Figure 1: PV-Battery power system connected to the grid

A. Modelling of the PV System and Design of MPPT Control Strategy

The electric power generated from the PV array fluctuates with the operating conditions and field factors such as the sun's position angle, irradiation levels and ambient temperature

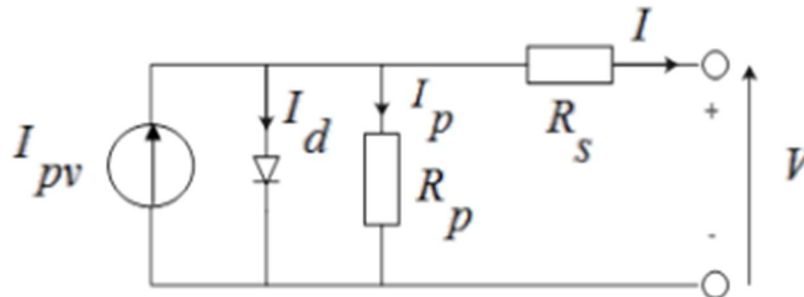

Figure 2: Single-diode equivalent circuit of a PV cell

A solar cell can be represented as a current source model, as shown in Fig. 2. Applying Kirchhoff's current law, the terminal current of the cell is [4]:

$$I = I_{pv} - I_d - I_p \quad (1)$$

$$I_p = V + R_s I / R_p \quad (2)$$

The light generated current of the PV cell depends linearly on the solar irradiation and is also influenced by the temperature according to the following equation

$$I_{pv} = (I_{pv,n} + K_I \Delta T) + \frac{G}{G_n} \quad (3)$$

Fig. 3 shows the basic circuit configuration of a DC-DC boost converter with an MPPT controller. A capacitor is generally connected between PV panel and the boost circuit to reduce high frequency harmonics [36]. MPPT algorithms have been proposed to automatically find the PV panel operating voltage that produces the maximum power output. Several MPPT techniques exist in the literature ranging from the simplest methods such as Perturb & Observe [3, 8] and Incremental Conductance [8, 9] to more sophisticated and complex ones. In this paper, an MPPT algorithm based on fuzzy logic control (FLC) is proposed. Similar FLC-based MPPT controllers were proposed in [6, 17]. The basic scheme of a FLC is shown in Fig. 4.

B. Maximum Power Point Tracking (MPPT)

Figure 3: Boost converter circuit and MPPT

The inputs are the error E and error change dE ; the output is the PWM duty cycle variation dD . Where K_E , K_{dE} and K_{dD} are scaling gains selected to achieve the desired transient and steady-state response characteristics [6, 12–14, 16]. The universe of discourse for each input and output variable is divided into three fuzzy sets defined by triangular membership functions and labelled as NS (Negative Small), Z (Zero) and NB (Negative Big) as shown in Fig. 5. The fuzzy rules used to determine the controller output. The defuzzification is based on the popular center of gravity method.

C. Impact of Irradiance and Cell Temperature

The impact of irradiance and cell temperature on I_{pv} - V_{pv} characteristic function is demonstrated in figures 4 & 5, separately in figure 4. Demonstrates that the energy resultant changes straight with the irradiance. Figure 5. Demonstrate that the utmost resultant energy from the cluster diminishes in light of the fact that the temperature increments.

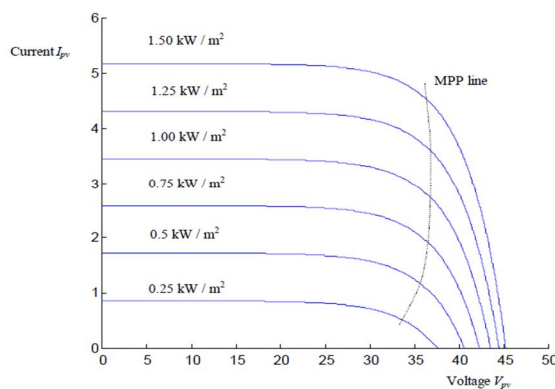

Figure 4: Impact of irradiance on the I-V characteristic at steady cell temperature

Figure 5: Impact of temperature on the I-V characteristic at steady irradiance

D. Power Stage in Boost Converter

Figures 6 shows improved forms of both the boost and buck converters. Just the force stage is appeared; a total controller requires more hardware to direct the result. We will begin by taking a gander at the buck. Note that single side of the inductor is associated with yield hub. Since no DC current can course through the yield capacitor, the complete burden current moves through the inductor. The alternative side of the inductor is linked to the regular hub in middle of the MOSFET and diode.

Figures 7 & 8 shows that the inductor and MOSFET current in CCM. On and off chance that we maintain a strategic distance from the, little three-sided swell, it is easy to see that the pinnacle MOSFET current is virtually similar as the heap current. This makes it simple for the controller producer to define the utmost burden current that the controller can flexible. Not with standing of the i/p or o/p V, the MOSFET can be measured for the most noteworthy burden current.

Likewise, as far as possible the present limits are often arranged just above this utmost value. So, the utmost MOSFET current rating of a buck is that the greatest burden current rating. As an illustration the LM43603 is evaluated for 3A on the info sheet. This is the utmost load I for this gadget. This isn't the situation for a lift converter. Note from figures 6 that the inductor is associated from the info supply to the normal hub between the MOSFET and diode. Along these lines the height MOSFET current is presently almost adequate to the info current, not the heap current. We will see that the info I relies upon the info and yield V's of the converter. The boost regulator remains rated supported the utmost MOSFET current but this doesn't represent the utmost load current, like the buck. The easiest approach to measure the information I of a boost controller is to utilize the energy balance condition.

Figure 6: Configuration of Boost Converter

Figure 7: Inductor current

Figure 8: MOSFET current

For a DC/DC converter, the i/p and o/p energies are only the merchandise their particular I's and V's. Adding the 3-sided ripple current, we show up at below equation 5.

$$P_{IN} = \frac{P_{OUT}}{\eta} \quad (4)$$

$$I_{IN} = I_{OUT} \cdot \left(\frac{V_{OUT}}{V_{IN}} \right) \cdot \frac{1}{\eta} + \frac{\Delta I}{2} \quad (5)$$

III. BATTERY ENERGY STORAGE SYSTEM (BESS)

A. Li-Ion Battery Model

The modelling approach is based on the equivalent circuit of the battery shown in Fig. 9. Where R represents the conducting resistance and the resistance from leading wires, R1 and C1 represent effects caused by mass transport, R2 and C2 represent effects caused by the charge transfer and the electrochemical double layer. The model will therefore include a State of Charge (SOC) controlled voltage source and its equivalent impedance.

Figure 9: Equivalent circuit based Li-ion battery

B. Battery Control System

The objective of the control system is to regulate the battery current in order to obtain the required power. Charging and discharging current limits and maximum SOC limitations are also included in the model. The BESS is connected to the DC grid via a bi-directional Buck-Boost DC/DC converter, as shown in Fig. 10. The BESS will operate in charging, discharging or floating modes depending on the energy requirements and these modes are managed according to the DC bus voltage at the BESS point of coupling. Consequently, the BESS is required to provide necessary DC voltage level under different operating modes of the microgrid. When charging, switch Q2 is activated and the converter works as a boost circuit; otherwise, when discharging, switch Q1 is activated and the converter works as a buck circuit. When the voltage at the DC link is lower than the voltage reference, switch Q1 is activated.

Figure 10: Battery with bi-directional buck-boost DC/DC converter

Alternatively, when the voltage at the DC link is higher than the voltage reference, switch Q2 is activated. The PV-battery system response to transient variations is characterized by an inherent time constant. In such cases, capacitors along the DC grid can act as virtual inertia to supply the shortfall or absorb the surplus of energy. Neglecting the losses in the power converters, battery, filtering inductors and transformer and also the harmonics due to switching actions, the power balance of the integrated hybrid distributed generation system (DGS) with energy storage is governed by:

$$V_{dc} \dot{i}_{dc} = C V_{dc} \frac{dV_{dc}}{dt} = P_{PV} + P_{bat} - P_{Load} \quad (6)$$

IV. SIMULATION IMPLEMENTATION

In this article, the proposed control scheme used MPPT to control the DC voltage of a three level (NPC) inverter connected to the hybrid (PV-battery) system integrated into the grid. It is evaluated using MATLAB/Simulink software under variable load conditions. The amount of power generated/supplied by the PV array depends on the solar irradiation $G = 1000 \text{ W/m}^2$ and temperature $T = 293 \text{ K}$. The proposed system is operated in three possible operating modes depending on the variable load. Simulation blocks diagram representation as shown in Fig 11.

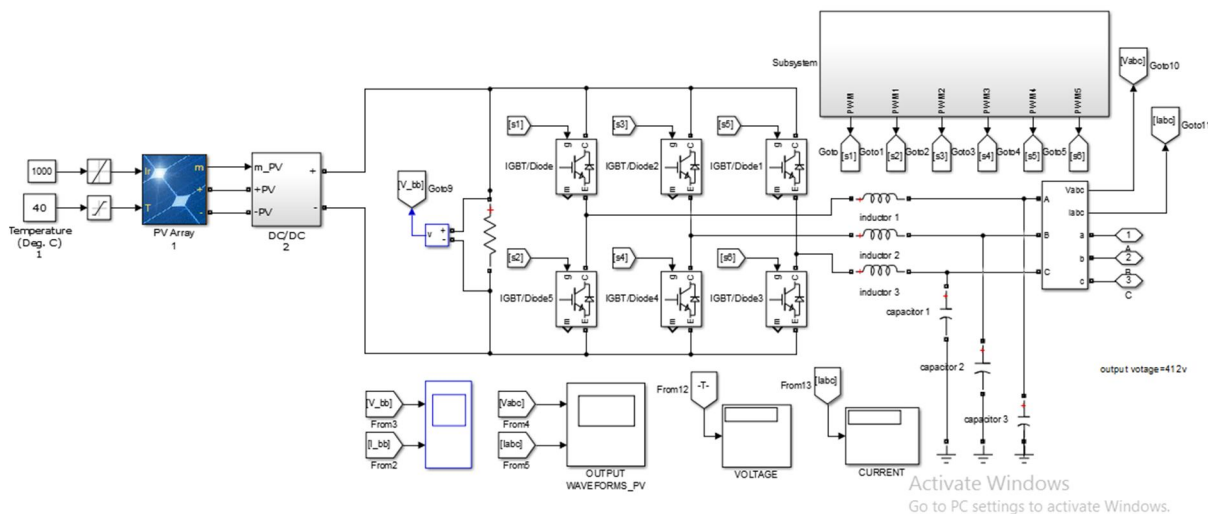

Figure 11: Simulation Implementation

Figure 12: Battery SOC Simulation

Figure 11. Shows the Simulink model of Multifunctional Control for PV Integrated Battery Energy Storage System. Operating mode 1: when the grid and the PV generated the same powers to the load between $t = 0$ to 0.5 s assuming the PV power generating system is greater than the difference between the load and the grid power ($PPV \geq P_{Load} - P_{grid}$) and assuming the battery is not fully charged. The excess power of the PV array also simultaneously charges the battery bank. Battery SOC as shown in Fig. 12. Operating mode 2: when ($P_{Load} \geq 0.11$ MW) the PV generated the nominal power to the load so the grid supplies power to the grid between $t = 0.5 \dots 1$ s, in this mode, the battery is able to provide power to ensure the stability of the DC-link voltage. Operating mode 3: when ($P_{Load} \leq 0.11$ MW) the grid supplies power to the grid between $t = 1 \dots 1.5$ s. In this mode, the PV panels can simultaneously supply to power to the load, to the battery and to manage the DC-link voltage of the three-level NPC inverter

V. SIMULATION RESULTS

The SOC of a battery, that is, its remaining capacity, can be determined using a discharge test under controlled conditions. The voltage method converts a reading of the battery voltage to the equivalent SOC value using the known discharge curve (voltage vs. SOC) of the battery. The battery minimum state of charge is the relative state of charge below which the storage bank is never drawn, specified as a percentage of the total capacity. Most rechargeable batteries are not meant to be fully discharged. In fact, fully discharging some batteries can permanently damage them.

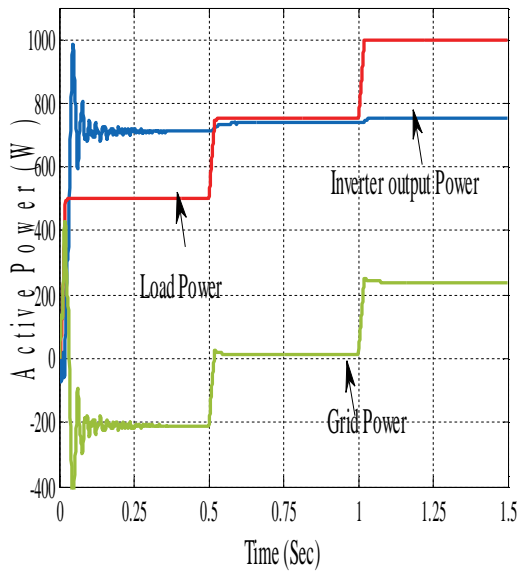

Figure 17. Boost Converter Load, Inverter, and Grid Active Power Profile

Figure 19: Bi-Directional Converter Output Voltage and Current

If the state of charge value is less than or equal to 30%, then the battery operates at charging mode. Boost converter charge the battery by solar power. If state of charge value is higher than or equal to 80%, then the battery operates at discharge mode. Bi-directional converter boosts the battery voltage and delivers to load. Battery state of level reduces and corresponding voltage delivers is charging and discharging using solar power.

VI. CONCLUSION

The article focused on the control strategy for a hybrid (PV-battery) system linked to the grid through a three-level NPC inverter. In this study, the PV array was connected to the DC bus through a boost converter to force the PV output to follow the maximum power. The DC bus then connected to the AC bus through a three-phase three-level DC-AC inverter. A DC/DC bidirectional converter connected between the DC-link and the battery was used to charge/discharge the battery. The simulation results show that the proposed three level NPC inverter has demonstrated its ability to provide a high-quality injected current from the PV array into grid. We have provided stability of the DC bus voltage against variation of the load. These results show the efficiency of the management and the controls used for this hybrid system.
