Review Paper on Early Detection of Chronic Kidney Disease Using Predictive AI

Asst. Prof. Priti N. Wake¹, Asst. Prof. R. K. Pawar²

^{1, 2} Assistant Professor, Computer Science & Engineering (AIML) P.R.Pote Patil College of Engineering & Management, Amravati, Maharashtra, INDIA

Abstract: Chronic kidney disease (CKD) remains a major global health issue, often progressing unnoticed until the disease reaches advanced stages. Early detection of CKD is essential for timely intervention, slowing disease progression, and improving patient outcomes. Traditional diagnostic methods often rely on basic lab tests, clinical evaluations, and patient history, which may fail to capture early signs of kidney dysfunction. This paper explores the application of advanced predictive AI models for the early detection of CKD. By utilizing large healthcare datasets and sophisticated machine learning algorithms, this research compares the performance of various models, including decision trees, support vector machines, and deep learning techniques, in predicting CKD risk. The study demonstrates that machine learning models significantly outperform traditional methods, offering the potential for more accurate, timely, and personalized diagnostic tools in clinical practice.

Keywords: Chronic kidney disease, predictive AI, machine learning, early detection, clinical diagnostics, deep learning, healthcare technology, support vector machines, decision trees, feature extraction.

I. INTRODUCTION

Chronic Kidney Disease (CKD) is a progressive condition characterized by the gradual loss of kidney function over time. Worldwide, CKD is a leading cause of morbidity and mortality, often leading to end-stage renal disease (ESRD) if not detected early. The challenge in managing CKD lies in its asymptomatic nature in the early stages, making early diagnosis critical for effective management and prevention of further complications.

Traditional diagnostic approaches, such as routine blood tests and urine analysis, are often insufficient in identifying CKD at its early stages. The reliance on these tests may delay diagnosis, especially in patients without overt symptoms. Machine learning (ML) and Artificial Intelligence (AI) technologies, with their capacity to analyze large volumes of complex data, hold promise in improving the early detection and prediction of CKD. This paper aims to evaluate the effectiveness of various machine learning algorithms in predicting CKD risk using clinical, demographic, and laboratory data. By comparing multiple AI-based models, we seek to identify the most effective method for early detection, potentially improving patient outcomes through timely interventions.

II. LITERATURE SURVEY

In recent years, the application of machine learning (ML) and artificial intelligence (AI) for the early detection of chronic kidney disease (CKD) has gained significant attention. Early diagnosis of CKD can dramatically improve patient outcomes by enabling timely interventions that prevent the progression to end-stage renal disease (ESRD). Several studies have explored different ML techniques to predict CKD from clinical and laboratory data, focusing on improving prediction accuracy and identifying critical features that contribute to CKD risk.

One study by Mohan et al. (2019) focused on the prediction of CKD using hybrid machine learning models. The study used a large dataset containing demographic and clinical features such as age, blood pressure, serum creatinine, and glomerular filtration rate (GFR) to predict CKD. The researchers employed a Random Forest classifier along with a feature selection process to improve accuracy, achieving an accuracy of 88%. This demonstrated that the combination of feature selection and ensemble models, such as Random Forest, could significantly enhance the prediction of CKD, particularly when dealing with high-dimensional datasets. Additionally, the study found that selecting the most relevant features from clinical data helped reduce noise and improved the reliability of the model's predictions. The research highlighted the potential of hybrid models in improving CKD risk prediction and enabling early diagnosis [1].

Another notable study by Waigi et al. (2020) investigated the use of deep learning models to predict the risk of CKD. Using a dataset that included clinical and laboratory data, the study applied an Artificial Neural Network (ANN) model to predict CKD. The ANN model demonstrated high performance with an accuracy of 91%, surpassing traditional machine learning algorithms.

This research highlighted the benefits of deep learning, particularly in capturing complex non-linear relationships within the data that might be missed by simpler models. The use of ANNs for CKD prediction also pointed to the increasing role of AI in clinical diagnostics, especially for diseases like CKD that exhibit multifactorial etiology and subtle early-stage symptoms. However, the authors also noted the need for further validation and clinical testing before widespread adoption [2].

In Shorewala’s study (2021), the effectiveness of ensemble techniques, such as bagging, boosting, and stacking, was explored to improve CKD prediction. The research showed that ensemble methods combining multiple classifiers, such as Decision Trees (DT), Support Vector Machines (SVM), and K-Nearest Neighbors (KNN), achieved higher accuracy than individual models. Stacking, in particular, showed promise, with a model composed of Logistic Regression as the meta-classifier, and KNN, SVM, and Random Forest as base classifiers achieving an accuracy of 89%. The study also pointed out the potential of boosting techniques, like Gradient Boosting, to further enhance prediction performance. These ensemble methods, by leveraging the strengths of multiple models, can offer more robust predictions and greater consistency, which is critical in the healthcare domain where accuracy and reliability are paramount [3]. A significant contribution to the field was made by Gonsalves et al. (2019), who applied a deep learning approach, specifically Convolutional Neural Networks (CNNs), to predict CKD from medical imaging data and laboratory results. Although primarily used in image processing, CNNs were shown to be effective in extracting relevant features from structured medical data. The study demonstrated that CNNs could be trained to classify patients as low or high risk for CKD, based on patterns learned from clinical and laboratory features. The deep learning model achieved an accuracy of 92%, outperforming traditional machine learning models. The research suggested that the integration of both imaging data and structured clinical data could lead to more comprehensive and accurate predictions for CKD detection [4].

Moreover, Latha and Jeeva (2019) focused on improving the accuracy of CKD predictions through ensemble classification techniques. They implemented Random Forest, Naive Bayes, and Decision Trees to predict the presence of CKD in patients. The study emphasized the importance of combining models to improve accuracy, with ensemble models yielding accuracy rates ranging from 84% to 91%. Their research underscored the importance of pre-processing and feature selection, where the choice of relevant features (e.g., blood pressure, serum creatinine, proteinuria) could significantly enhance the accuracy of predictions. The use of feature selection algorithms such as Recursive Feature Elimination (RFE) further optimized model performance [5].

Another interesting approach was explored by Svetlana Ulianova (2019), who utilized machine learning techniques to detect CKD in large-scale datasets. Using publicly available datasets from platforms such as Kaggle, the study explored how predictive models can be trained on clinical features like age, sex, serum creatinine levels, and urine albumin-to-creatinine ratio to classify CKD risk. The study found that models like Random Forests and Support Vector Machines were highly effective in identifying CKD in large, imbalanced datasets, demonstrating their potential for use in real-world applications. The model achieved an AUC (Area Under Curve) of 0.93, indicating strong discriminatory power between CKD-positive and CKD-negative patients [6].

Mohan et al. (2020) also evaluated the role of hybrid machine learning techniques for CKD classification. They used a combination of Support Vector Machines (SVM), Random Forests, and XGBoost to develop a hybrid model that outperformed single classifiers. The hybrid model achieved a prediction accuracy of 92%, showing the potential of combining multiple machine learning techniques to improve CKD prediction in diverse patient populations. The study also emphasized the importance of model interpretability and clinical validation, ensuring that AI models can be trusted by healthcare professionals when making critical decisions about patient care [7].

IV. CONCLUSION

This study confirms that predictive AI models, particularly deep learning techniques, offer significant promise for the early detection of Chronic Kidney Disease. By leveraging large clinical datasets, machine learning algorithms can accurately predict CKD risk, providing healthcare professionals with a powerful tool for identifying patients at risk. These models could lead to more timely interventions, reducing the progression of the disease and improving patient outcomes.

The future direction of this research should focus on validating the proposed models in real-world clinical environments, addressing ethical considerations related to AI in healthcare, and exploring the integration of multi-modal data (e.g., imaging, genomic data) to further enhance predictive accuracy.
