Studying the Variations of surface Roughness Parameters of Nitronic-60 to Extrusion Honing Process

H P Raju¹, Abhijith K. S²

¹Professor, ²PG. Scholar, Department of Mechanical Engineering, P.E.S.C.E, Mandya-571401, Karnataka state, India.

Abstract: *Extrusion Honing (EH) is also known as Abrasive Flow Machining (AFM) deburrs, polishes and radiuses surface and edges by flowing an abrasive media over these areas. The process is particularly used on internal shapes which are difficult to process by other machining techniques. The machine controls the extrusion pressure and the flow volume and speed. Since abrasive action occurs only in areas where the flow is most restricted, tooling is often used to direct the media to the appropriate areas. A variety of finishing results can be achieved with different abrasive types, sizes, concentrations and media viscosities. In the extrusion honing is a process in which a tool of abrasive laden putty which is to some extent a firm consistency; semi-solid state, is made to flow across or through the work piece in a constant pressure to carry out the process like cleaning, polishing, remove recast layers etc. In this work the experimental process is conducted using one-way extrusion honing machine and the process is carried out on Nitronic-60, one of the super alloys having high hardness and high strength properties which is machined to get good surface finishing.*

Keywords: *Deburrs, Extrusion Honing, abrasive, media viscosity, Nitronic 60, surface finish*

I. INTRODUCTION

Extrusion Honing (EH) is also known as Abrasive flow machining (AFM) was developed by the Extrude Hone Corporation, USA in 1960s as a method to deburr and polish difficult-to-reach surfaces and edges by flowing abrasive laden polymer with special rheological properties [1]. EH can be applied to an impressive range of finishing operations, providing uniform repeatable and predictable results. Experimental investigations have been carried out by various researchers to investigate the effects of process parameters like extrusion pressure, number of cycles, viscosity, abrasive concentration and grain size on the output responses namely, surface finish and material removal during EH.

Jain and Adsul [2] reported that softer material has higher material removal and more improvement in surface finish (ΔRa) compared to harder material.

Gorana et al. [3] reported that extrusion pressure, abrasive concentration and grain size affect the cutting forces, active grain density and finally reduction in surface roughness (Ra value).

In Extrusion Honing (EH), abrasive concentration, abrasive grit size, viscosity of the abrasive media, extrusion pressure, geometry of machining surface, are the factors which influence on material removal and surface roughness. Material properties like hardness and ductility also influence upon material removal and improvement in surface roughness. Abrasives with higher grit size give better surface finish with lower

Raju et.al [4] have reported that extrude honing of SG iron (600 grade) has been performed hydraulically actuated extrude honing set-up using a select grade of polymer as abrasive carrier medium. SiC grit of 36 mesh size is used as abrasive. The surface finish parameters were measured at two locations on entry side and exit side of the abrasive media. The results obtained show that extrusion honing process in 10 bar range shows good improvement in surface finish parameters is seen till seventh pass, beyond which the surface starts deteriorating. The extrusion honing process in the lower pressure range yields good results in finishing SG Cast Iron (600 grade). Out of roundness of extrude honed surface is improved, and Surface in the middle zone is better than the entry/exit zone due to better contact with the abrasive medium.

This process is capable of finishing regions which are difficult to reach by flowing abrasive which are mixed with polymer of special rheological properties. Extrusion Honing produces repeatable, uniform and predictable results based on a notable range of finishing operation. Some of the abrasive grains commonly used in Extrusion Honing process are Aluminium Oxide, Boron Carbide, Diamond and Silicon Carbide. In EH process, medium or tool used to machine the material comprises of polymer based on visco-elastic material matrix which is mixed with abrasive particle and additive, which is used to extrude different primitives of

work piece. While extruded through the passage which is formed by the work piece and tooling, this medium tries to finish the work piece surface selectively. Here in the process tooling plays the important role. So, the design of the fixture or tooling should be done carefully. One of property of the polymer is that the polymer chain holds the abrasive particle flexibly and moves them around in the direction of the extrusion pressure. Thus, the medium is used as a multi-point tool cutter which starts abrading the work piece surface. Extrusion process is one the most extended process used in wide range of industrial applications in the field of manufacturing which have different approaches of extrusion process. This finishing technique also reduces the human effort and provides the high-quality surface finish

II. EXPERIMENTAL DETAILS

Experiment conducted on one-way Extrusion honing machine built in Laboratory and surface parameters are evaluated for each trial. Surface roughness parameters measurements were taken at entry and exit positions for $\phi 6\text{mm}$, $\phi 8\text{mm}$ and $\phi 10\text{mm}$. Finally, SEM images of work pieces before and after the 10 EH passes were taken.

A. Work Material Details

Super alloy Nitronic-60 is an iron-based high temperature and high strength alloy. The following datasheet provides an overview of super alloy Nitronic-60.

1) Applications of Nitronic-60

- a) Automotive valves - can withstand gas temperatures of upto 1500°F for a minimum of 50,000 miles.
- b) Fastener galling - capable of frequent assembly and disassembly, allowing more use of the fastener before the threads are torn up, also helps to
- c) Eliminate corroded or frozen fasteners.
- d) Pins - Used in roller prosthetics & chains to ensure a better fit of parts (closer tolerance, non-lubricated) and longer lasting.
- e) Marine shafts - better corrosion than types 304 and 316, with double the yield strength.
- f) Pin and hanger expansion joints for bridges - better corrosion, galling-resistance, low temperature toughness, & high charpy values at sub-zero temps compared to the A36 and A588 carbon steels commonly used.

TABLE 2.1

Chemical composition of Nitronic-60

Element	Content (%)
Iron, Fe	58.47
Nickel, Ni	8 to 9
Chromium, Cr	16 to 18
Molybdenum, Mo	0.75
Manganese, Mn	7 to 9
Silicon, Si	3.5 to 4.5
Carbon, C	0.10

TABLE 2.2

Physical properties of Nitronic-60

Properties	Metric
Density	7.6gm/cm ³
Melting point	1375°C

TABLE 2.3
Mechanical properties of Nitronic-60

Properties	Metric
Tensile strength	724MPa
Yield strength	379MPa
Elongation at break	35%
Reduction of area	55%
Hardness, Brinell	205
Hardness, Knoop	330
Hardness, Rockwell C	33
Hardness, Vickers	318

B. Specimen Preparation

Nitronic-60 specimens of 25 mm diameter and length 12 mm with hole diameter of 6, 8 and 10 mm. The specimens were initially drilled using carbide drill bits and thoroughly washed with acetone to remove the clogged particles. Surface roughness parameters were measured using a surface roughness measuring instrument (Surfcom 130A) before conducting the experiment.

(a)

C. Preparation of Abrasive media

Abrasive media is prepared by thoroughly mixing Silicone carbide abrasives with silicone polymer using abrasive mixer. The volume fraction of Silicone carbide abrasives with silicone polymer used is 35%

D. Experimental Procedure

Initially the extrusion honing machine is switched “on”, the actuation of directional control valve in forward direction results in abrasive media to extrude through the specimen from one side and exits out at the other. After each trails the test specimens were thoroughly cleaned with acetone solution to remove clogged polymer and other dust particles and surface roughness parameter were measured at 2 locations (drill entry side and drill exit side) each at 3 position (120°C apart). This procedure is repeated for 10 passes and results were tabulated.

TABLE 2.4
Extrusion Honing Process Parameters

Parameters	Details
Number of passes	10
Hole diameter (mm)	6, 8, 10
Abrasive mesh size	36
Volume fraction of abrasives	35%
Pressure	60 bar
Temperature	Ambient
Stroke length	600

III. RESULTS AND DISCUSSION

The main aim of the present work is to remove roughness and to attain a fine surface finish by applying extrusion honing process on Nitronic 60. After each finishing cycle, the finished surface of specimens was evaluated for its surface finish parameters (Ra, Rt, Rz and Rpk). Graphs were plotted for the parameters obtained after each experimental for all specimens of diameter of 6 mm, 8 mm and 10 mm under consideration.

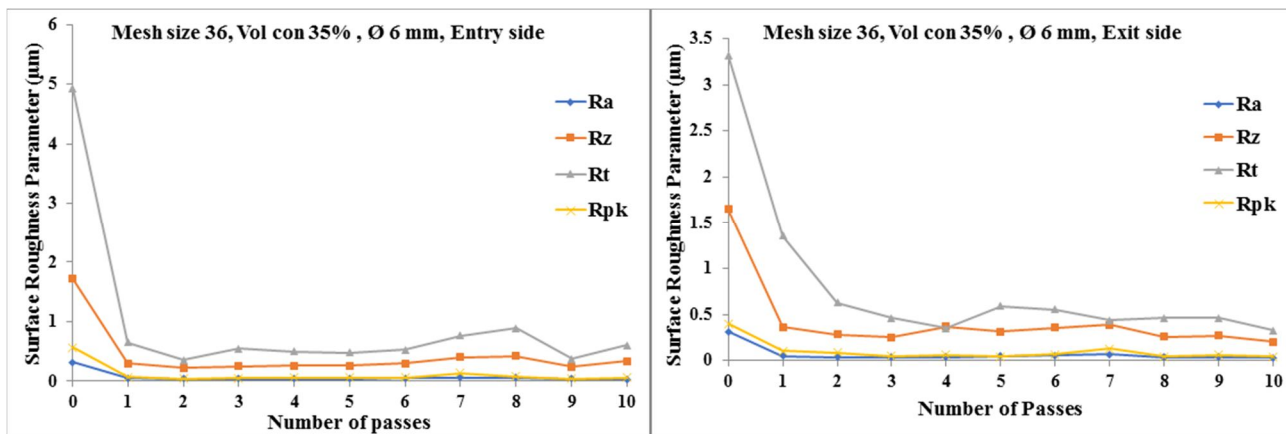

Fig 3.1: Surface roughness parameters v/s number of passes (a) Entry side, (b) Exit side

Fig 3.2: Surface roughness parameters v/s number of passes (a) Entry side, (b) Exit side

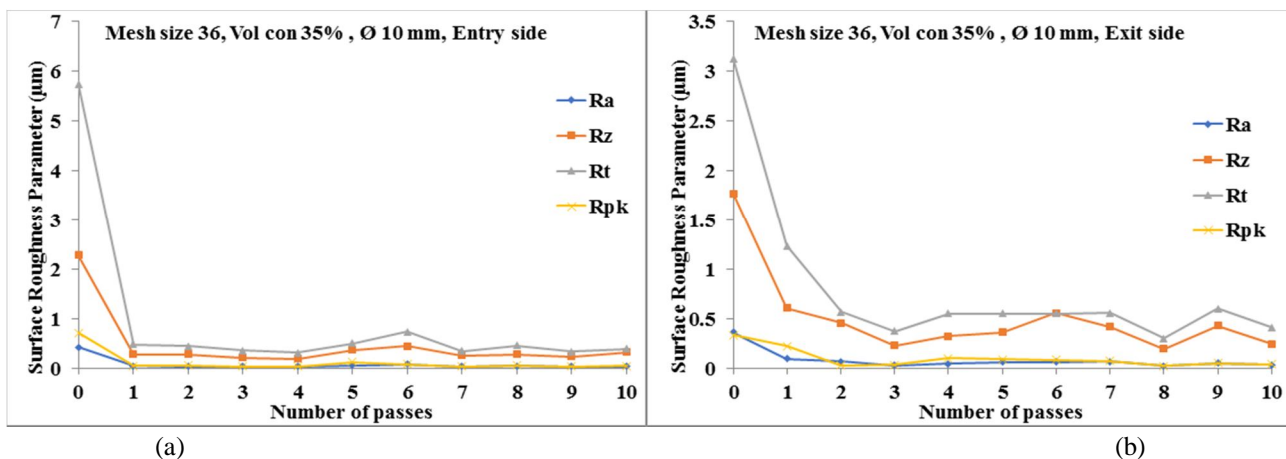

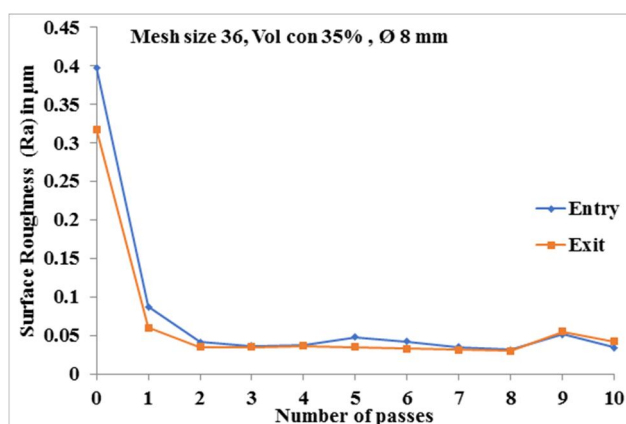

Fig 3.3: Surface roughness parameters v/s number of passes (a) Entry side, (b) Exit side

(a)

(b)

(c)

Fig 3.4: Surface roughness (Ra) at Entry and Exit side v/s number of passes; (a) Ø 6 mm, (b) Ø 8 mm and (c) Ø 10 mm

Fig 3.1, 3.2 and 3.3 represents the impact of honing on roughness parameter on both entry and exit sides of the specimen respectively. There exhibits a drastic decrease in the surface roughness parameters after 1st pass followed by a progressive reduction afterwards and attains core roughness between 3th to 6th pass, in later passes, surface deterioration can be seen. Fig 3.4 compares the surface roughness (Ra) achieved on both entry and exit side of the specimens. It can be seen that, Ra along exit side of the media is better than the entry side.

Fig 3.5: SEM images for 500 magnification; (a) 6 mm, Zero pass (b) 6 mm, Ten Passes (c) 8 mm, Zero pass (d) 8 mm, Ten Passes (e) 10 mm, Zero pass (f) 10 mm, Ten Passes

From the above SEM images (fig: 3.5), it can be seen that the uneven initial tool feed marks and macro surface irregularities of drilling operation have been effectively removed and replaced with a fine surface having a uniform lay.

IV. CONCLUSION

In the present study, Extrusion Honing of Nitronic 60 was done using a working medium developed using a select grade silicone polymer and silicon carbide (SiC) abrasive particles. The Extrusion Honed surface of each specimens were evaluated at three different points on both entry and exit side of the specimen with respect to medium entry. From the present study, following conclusion could be drawn,

- A. The present study shows that, working medium made of silicone polymer and SiC abrasives was able to produce a good surface finish on Nitronic 60.
- B. Surface finish increases greatly after first pass followed by a progressive improvement and once the surface attains core roughness, deterioration of surface sets in.
- C. Surface finish of specimen along exit side is better than the entry side.
- D. The uneven Surface irregularities and lay pattern have been effectively replaced with fine surface having a uniform lay.

V. ACKNOWLEDGEMENT

The authors would like to thank AICTE, New Delhi India, for their financial support to the project “Micro Finishing of Internal Primitives through Extrusion Honing Process” No.8023/BOS/RPS-123/2006-07. Authors also would like to thank Mr.N L Murali Krishna, professor, Department of Industrial and Production Engineering, PESCE Mandya for kind help during experimentation.
