**Abstract:** In this paper many spread-spectrum schemes, several of which are new, have been designed and implemented for conducted-noise reduction in DC-DC converters. A field programmable gate array (FPGA) has made substantial improvements in price and performance throughout the past few years. The implementation of the schemes has been accomplished by using FPGA-based controller. A breadboard circuit has been built-up for investigating the effect of all the proposed schemes on conducted-noise spectrum in DC-DC converters. Furthermore, a comparative study has been carried-out to reach the most efficient scheme in spreading the conducted-noise spectrum. Experimental results show that randomizing each of carrier frequency, duty-ratio, and the pulse position parameters significantly improves the conducted-noise spectrum and effectively reduces the noise peaks at both high and low frequency ranges.

## I. INTRODUCTION

DC-DC converters are important in portable electronic devices such as cellular phones, laptop computers, and electric vehicles, which are supplied with power from a DC power source such as batteries, photovoltaic cells, or fuel cells. Such electronic devices often contain several sub circuits with each sub-circuit requiring a unique voltage level different from that supplied by the source. Switching power converters have been reported to generate common-mode and differential-mode conducted-noise in addition to radiated-noise. They may cause serious problems by generating such switching noise. Although switching converters produce significant amounts of switching noise, they are also required to operate inside electromagnetic interference (EMI) sensitive applications. This research aims to reduce the switching noise produced by DC converters. Traditional tools for EMI suppression are related to the use of filters and shielding techniques. But these tools are bulky and require expensive passive components, which makes them unsuitable for space-limited and price-sensitive portable devices. Alternative, pre-emptive EMI mitigation techniques eliminate the need for EMI filters by spreading the switching converters noise over a frequency range. By using these techniques, the noise generated by the Switching-Mode Power Supplies (SMPS) can be spread across a well defined frequency band. As a result, the average spectral power density of the broadband noise can thus be drastically reduced. FPGA is an attractive hardware design option. It has made substantial improvements in price and performance throughout the past few years. For an excellent overview of the classical and recent developments in FPGA technology, focusing on industrial control system applications. Although FPGA implementation is now widespread in a range of military, defense, and signal processing applications, it is much flexible than analog control, becoming lower cost, and applicable for power supply applications. The implementation of the spread-spectrum schemes has been accomplished by using FPGA-based digital controller. The paper is organized as follows: Section II presents spread-spectrum schemes in DC-DC converters. The design and implementation of the proposed FPGA-based controller which includes pseudorandom streams generator and digital pulse-width modulator are addressed in section III. Section IV describes the details of the experimental test circuit. Experimental results and discussion are presented in section V. Finally, conclusions and future work have been presented in section VI.

## II. SPREAD-SPECTRUM SCHEMES IN DC-DC CONVERTERS

According to Fig. 1,  $T_k$  is the duration of the  $k$ th cycle,  $\alpha_k$  is the duration of the on-state within this cycle, and  $e_k$  is the delay from the starting of the switching cycle to the turn-on within the cycle. Note that the duty ratio is  $d_k = \alpha_k / T_k$  and the Switching frequency  $F_k = 1/T_k$ .

# International Journal for Research in Applied Science & Engineering Technology (IJRASET)

Fig. 1. Randomization parameters in the switching signal.

The switching function  $q(t)$  consists of a series of such switching cycles. In order to spread the frequency spectrum of the switching noise,  $\{F_k, d_k, \text{ or } \epsilon_k\}$  can be randomized. Table I summarizes all the possible schemes that can be carried-out for this purpose. Some randomization schemes used in power electronics are:

Randomized pulse position modulation (RPPM):  $\epsilon_k$  changes;  $F_k$ , and  $d_k$  are fixed;

Randomized pulse width modulation (RPWM):  $d_k$  changes;  $F_k$ , and  $\epsilon_k$  are fixed;

Randomized carrier frequency modulation with fixed duty ratio (RCFMFD):  $F_k$ , changes;  $d_k$ , and  $\epsilon_k$  are fixed;

Randomized carrier frequency modulation with variable duty ratio (RCFMVD):  $F_k$ , and  $d_k$  change;  $\epsilon_k$  is fixed.

Randomized duty ratio, randomized pulse position modulation with fixed carrier frequency (RDRPPMFCF):  $d_k$ , and  $\epsilon_k$  change;  $F_k$  is fixed;

Randomized carrier frequency, randomized pulse position modulation with fixed duty ratio(RCFRPPMFD):  $F_k$ , and  $\epsilon_k$  change;  $d_k$  is fixed;

Randomized carrier frequency, randomized duty ratio, with randomized pulse position modulation (RRRM):  $F_k$ ,  $d_k$ , and  $\epsilon_k$  change.

TABLE I  
 THE RANDOMIZATION PARAMETERS FOR THE SCHEMES.

Case	Scheme	Randomization Parameters			$\alpha_k$	Remarks
		$F_k$	$d_k$	$\epsilon_k$		
(a)	PWM	Const.	Const.	Const.	Const.	Basic
(b)	RPPM	Const.	Const.	Rand.	Const.	Ad.*
(c)	RPWM	Const.	Rand.	Const.	Rand.	Ad.*
(d)	RDRPPMFCF	Const.	Rand.	Rand.	Rand.	New
(e)	RCFMFD	Rand.	Const.	Const.	Rand.; Synch.	Ad.*
(f)	RCFRPPMFD	Rand.	Const.	Rand.	Rand.; Synch.	New
(g)	RCFMVD	Rand.	Rand.	Const.	Rand.	Ad.*
(h)	RRRM	Rand.	Rand.	Rand.	Rand.	New

### III. DESIGN AND IMPLEMENTATION OF THE PROPOSED FPGA-BASED CONTROLLER

This section presents the design and implementation of the proposed FPGA-based controller which includes pseudorandom stream generator and digital pulse-width modulator.

#### A. Pseudorandom Streams Generator

As discussed in the previous section, in order to spread the noise spectrum,  $\{F_k, d_k, \text{ or } \epsilon_k\}$  can be randomized. Hence three random number generators are needed to realize all the addressed schemes.

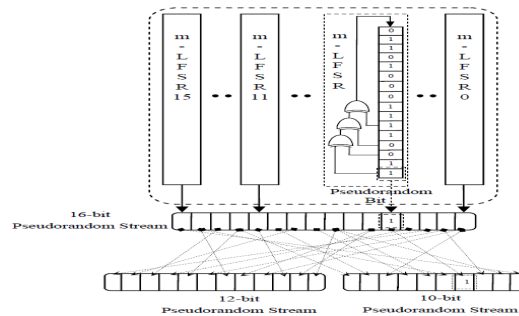

Fig. 2. The proposed pseudorandom streams generator.

A pseudorandom streams generator has been constructed for this purpose. As shown in Fig. 2, the proposed construction uses several maximum length linear feedback shift registers (m-LFSRs) in parallel. The use of m-LFSRs is due to the fact that the sequence generated by the m-LFSRs has a maximum period. For different m-LFSRs output bits, different initial contents of m-LFSRs (seeds) have been used.

## International Journal for Research in Applied Science & Engineering Technology (IJRASET)

The random carrier frequency scheme for dc-dc converters is examined and compared with the standard PWM scheme and the FM scheme. The feature of the RCF scheme is that it inherently ensures constant duty cycle operation in the dc-dc converter. The variation of the output voltage is not as significant as the RPWM and RPPM schemes and therefore allows simple feedback control design. At the same time, the power spectra of the converter input current and the switch voltage will spread over wide frequency range so that no harmonic of the differential mode and common mode conducted EMI can in principle be reduced. The RRRM scheme attains the best performance.

Fig 4: Generation of RRRM signal

It provides the highest conducted-noise peak reduction at the low frequency range. Furthermore, it decreases the conducted-noise peak at the high frequency range by 7.8dB. The switching frequency, as a randomization parameter, is more efficient in spreading the conducted-noise than the duty-ratio or the pulse position parameters

## V. CONCLUSIONS

Many spread-spectrum schemes, several of which are new, have been designed and implemented using FPGA for conducted-noise reduction in DC-DC converters. Moreover, the effect of using such schemes on the conducted-noise characteristics of the converter has been experimentally investigated and provided the conclusions that The RRRM scheme attains the best performance. It provides the highest conducted-noise peak reduction at the low frequency range. Due to the switching frequency, as a randomization parameter. It is more efficient in spreading the conducted-noise than the duty-ratio or the pulse position parameters. Furthermore, it decreases the conducted-noise peak at the high frequency range by 7.8dB as compared with RPWM scheme gives the worst performance. It poorly improves the conducted-noise spectrum at the high frequency range. Moreover, it increases the conducted-noise peak at the low frequency range and this method will be implemented in FPGA for real time analysis and it would give more detailed analysis of the noise in the DC-DC converters.
