Analysis of Different Lubricants in Gearbox Performance using Ansys

Rajput Arvind¹, Vatsal Shah²

¹Gujarat Technological University, ²Chandubhai s patel institute of technology(CHARUSAT)

Abstract—In the present paper CFD based investigation has been reported in order to study about the power losses for different gear oils in operating conditions and alternative of it. It has been observed that there is significant change during working condition of gearbox. During working condition heat is generated, when two teeth meshes together. Because of heat generation inside the gearbox, the viscosity of the oil decreases and ultimately there is change in the oil properties. This change in gear oil properties(i.e decrease in gear tooth hardness, oil level and speed of gear and increase in vibration, noise, wear and power loss.) These losses are the sum of squeezing, churning and windage power losses. In order to predict the power losses in the gearbox performance the analysis is done using software ANSYS12 and a general idea about the gearbox model is created using modelling software SOLID WORKS 2012.

Keywords— Gear, Gearbox, Lubricants, CFD, SOLID WORKS, Power Loss.

I. INTRODUCTION

Designing and choosing a gearbox for different industrial application are must to consider some performance specifications. These important specifications for gearbox designing and selection are gear ratio, torque, maximum input power, maximum input rpm, shaft alignment. The gear ratios can be defined as the relationship between the number of teeth on two different gears meshed together, the circumference of two pulleys connected with a drive belt. Torque is a rotational force. It is force multiplied by perpendicular distance. Power in mechanical systems is the combination of forces and moments. In particular, power is the product of a force on an object and the object's velocity, or the product of a torque on a shaft and shaft's angular velocity. A revolution per minute is a measure of the frequency of a rotation. It annotates the number of turns completed in one minute around a fixed axis. It is used as a measure of rotational speed of a mechanical component. The rapid advance made in computer hardware and software led to significant developments in FEA software. FE programming gas emerged as a specialized discipline which requires knowledge and experience in the diverse areas such as FE technology including foundations of machines, and numerical analysis on the one hand and the computational skills in areas of software technology including programming techniques, data structure, database management and computer graphics on the other hand.

II. AIMS

Analysis of heat generation in gearbox using ANSYS[1]

Modelling of gearbox[2]

Analysis of temperature change in gearbox using ANSYS[3]

Analysis of power losses in gearbox using ANSYS[4]

Analysis of different lubricant in gearbox using ANSYS[5]

III. EXPERIMENT WORK

Modelling is 3D solids. Solid modelling is distinguished from related areas of geometric modelling and computer graphics by its emphasis on physical fidelity. Together, the principles of geometric and solid modeling form the foundation of computer-aided design and in general support includes creation, exchange, visualization, animation and interrogation of digital models of physical objects. Solid works is basically computer graphics system for modelling various mechanical designs, performing related design and manufacturing operations. The system uses a 3D solid modelling system as the core, and applies the feature base parametric modelling method. The Solid works was designed to begin modelling of entities by using computer. In Solid works the design engineers begin with features and design criteria for creation of modelling. Solid works features are process plans with embedded intelligence and it is easy to use while at the same time powerful enough to most complex geometry.[1]

International Journal for Research in Applied Science & Engineering Technology (IJRASET)

The Gear box model is prepared in solid works 2012 software as per gear specification. Various parts of gearbox and assembly are shown in Fig. 1 to 3.[2]

IV. CFD ANALYSIS

CFD can be used to determine the performance of a component at the design stage, or it can be used to analyse difficulties with an existing component and lead to its improved design. For example, the pressure drop through a component may be considered excessive. The first step is to identify the region of interest. The geometry of the region of interest is then defined. If the geometry already exists in CAD, it can be imported directly. The mesh is then created. After importing the mesh into the pre-processor, other elements of the simulation including the boundary conditions (inlets, outlets, etc.) and fluid properties are defined. The flow solver is run to produce a file of results which contain the variation of velocity, pressure and any other variables throughout the region of interest. The results can be visualized and can provide engineer with an understanding of the behaviour of the fluid throughout the region of interest.

A. Prepare Model Gearbox

The assembly modal of gearbox made in solid works 2012 is converted into STEP file and imported in ANSYS workbench is as shown in fig. 4

Fig.4 Assembly modal of gearbox

B. Meshing

FEA software typically uses a CAD representation of the physical model and breaks it down into small pieces called finite “elements” (think of a 3-D puzzle). This process is called “meshing”. The higher quality of the mesh (collection of elements), is a better mathematical representation of the physical model. ANSYS workbench simulation provides two forms of automated meshing: Fully automatic and manually directed automatic. Both forms employ a fault-tolerant philosophy and it means that, if a problem occurs, at least 12 attempts of automatic trouble-shooting are made before the meshing fails and tags the area of difficulty with a label. The Manual directed means that the user may specify meshing over rides on specific areas of a part or the baseline mesh density on entire parts that differ from other parts within the assembly, either for accuracy or efficiency purposes. Here in current work the fully automatic meshing of gearbox is done. The element chosen for meshing by ANSYS is ten nodes tetrahedral shown in fig.5 . This element is good for meshing in curvature area.[1]

Numbers of nodes and elements used for meshing are listed in table 1 below[2]

Table 1. Mesh Information for CFX

Domain	Nodes	Elements
Gear	5347	23913
Castor oil	23680	124330
All Domains	29027	148243

C. Material Property

Materials in the Workbench are imported from material library available in ANSYS database. If the material is not available in material library then it is required to define manually. Here in this experiment, work for doing Computational Fluid Dynamics(CFD) analysis of Castor oil in gear box the property of Castor oil is imported manually as shown in fig 6.

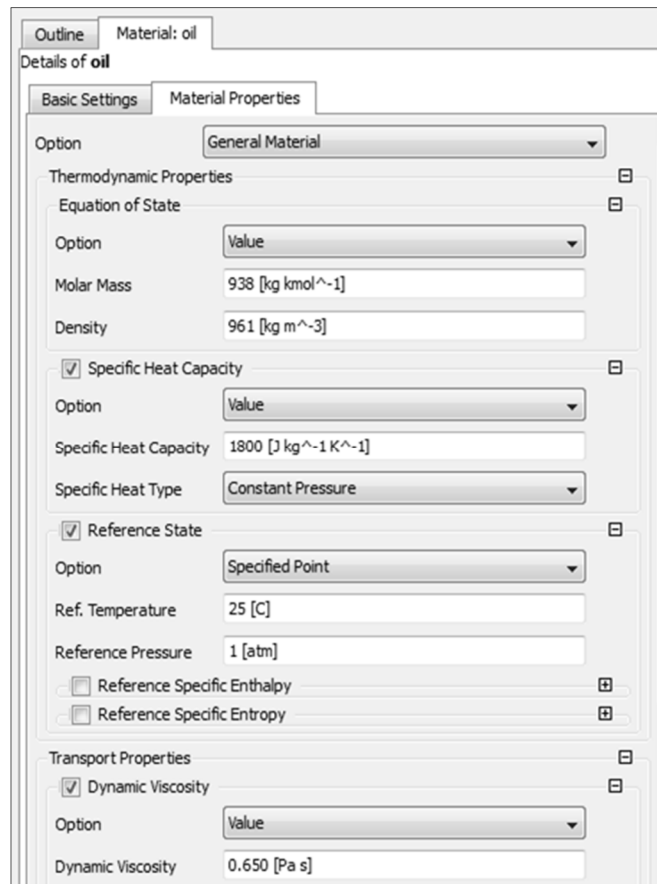

Fig. 6 Castor oil material property

International Journal for Research in Applied Science & Engineering Technology (IJRASET)

D. Boundary Condition

The boundary condition in Pre processor is very important for getting approximate result nearer to actual condition. In present work the boundary condition is defined as domain in pre processor. The first domain is defined as gear oil and second is a gear. The gear is a rotating domain and speed of rotation is 1450 rpm. This rotation effect of gear domain is transferred to the gear oil so it is also working as rotating domain.

V. RESULTS AND DISCUSSION

A. Input Power

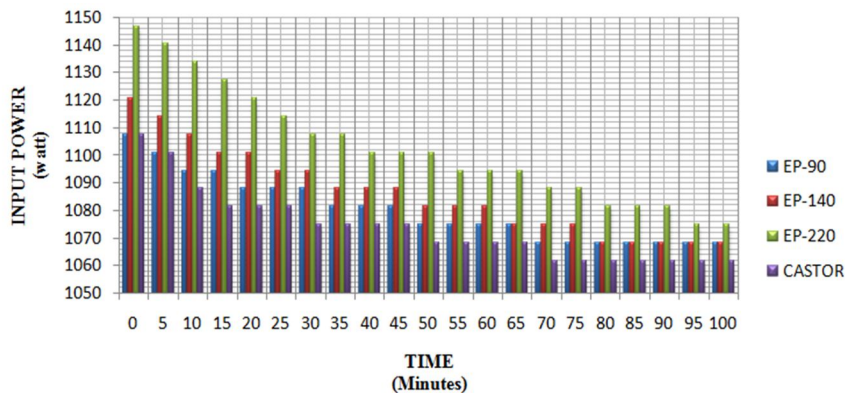

Fig. 10 Graph of input power vs. time

International Journal for Research in Applied Science & Engineering Technology (IJRASET)

From the above graph of input power vs. time it is seen that initially the required input power for the gear box is different as different types of the oil. The EP-220 gear oil requires higher initial input power compared to other oil. While EP-90 and Castor oil have required very less initial power. Also from the graph it is seen that the required input power reduces with increase in running time of gear box for all oil. This reduction of the input power with respect to running time of gear box is due to increase in temperature of the gear oil which causes the reduction of the viscosity of the oil.

B. Output Power

Fig. 11 Graph of output power vs. time

From the above graph of output power vs. time it is seen that initially the output power for the gear box is different as different types of the oil. The EP-220 and EP-140 gear oil have initially less output power compared to other oil. While the EP-90 and Castor oil have initial very high output power. Also from the graph it is seen that the output power increases with increase in running time of gear box for all oil but after 35 min it becomes same for all oil. The EP-220 oil takes more time compare to other types of oil for reaching maximum power output because its viscosity is very high compared to other oils and that causes churning effect in gear rotation.

C. Current

Fig. 12 Graph of current vs. time

From the above graph of current vs. time it is seen that initially the required input current for motor is different as different types of the oil. The EP-220 gear oil has required higher initial input current compared to other oil. While EP-90 and Castor oil have required less initial current. Also from the graph it is seen that the required input current reduces with increase in running time of gear box for all oil. EP-90 and EP-140 input current is same after 80 min. This reduction of the input current with respect to running

International Journal for Research in Applied Science & Engineering Technology (IJRASET)

time of gear box is due to decrease of viscosity with increase in oil temperature.

D. Temperature

Fig. 13 Graph of temperature vs. time

From the above graph of temperature vs. time it is seen that the initial temperature for all the gear oil is nearly same. The EP-220 gear oil has higher temperature compared to other oil. While the EP-90 has less temperature compared to other type oil. Also from the graph it is seen that the temperature increases with increase in running time of gear box for all oil. This increasing of temperature with respect to running time of gear box is due to friction between the oil and gear meshing.

E. Power Losses Due to Oil

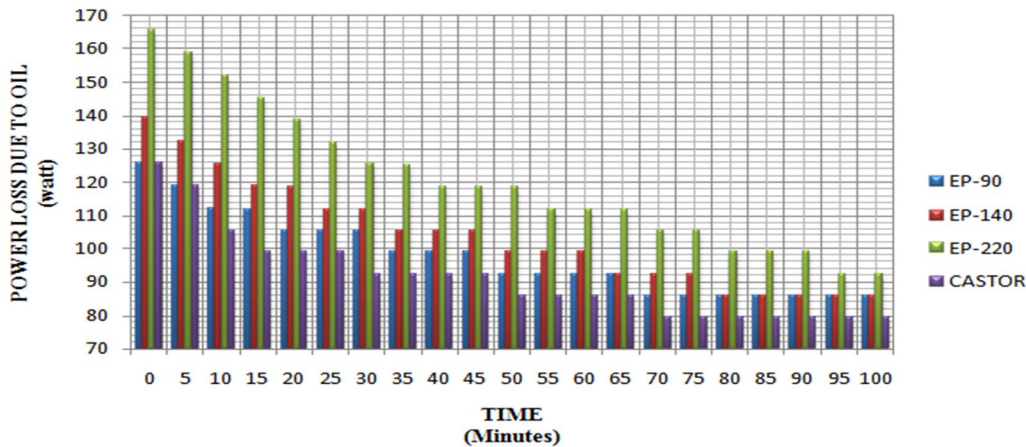

Fig. 14 Graph of power loss due to oil vs. time

From the above graph of power loss due to oil vs. time (Fig.14) it is seen that initially the power loss due to oil for the gear box is different as different types of the oil. The EP-220 gear oil has initially higher power loss compared to other oil. While the EP-90 and the Castor oil have very less initial power loss. Also from the graph it is seen that the power loss is decreased with increase in running time of gear box for all oil and Castor oil power loss is less than other type of oils. EP-90 and EP-140 gear oil has same power loss after 80 min. This reduction of the power loss with respect to running time of gear box is due to increase in temperature of the gear oil which causes the reduction of the viscosity of the oil, decrease requirement of initial current, input power and increase output power.

VI. CONCLUSION

The CFD analysis for find out the power losses in gear box due to different gear oil (EP-90, EP-140, EP-220, Castor) is carried out for 100 min. from the experiment it is concluded that:

The input power decreases with increase in gear running time for all the gear oil. The EP-220 having very high input power during the hole running time of the gear box, while the castor oil having less input power compared to all other gear oil in gear running

International Journal for Research in Applied Science & Engineering Technology (IJRASET)

time. [1]

The output power is increasing with increase of the gear running time but after 35 min it becomes maximum for all the gear oil. The EP-220 has required more time compared to other oil for reaching maximum output power, while the castor oil has required very less time to reach at maximum output power compared to other gear oil.[2]

The temperature of the gear oil is increasing with increase of the gear running time. The EP-220 having high temperature of oil compare to other gear oil, while the EP-90 oil having less temperature compare to other gear oil. [3]

The power loss due to the gear oil decreases with increase in gear running time for all the gear oil. The EP-220 having higher power loss compared to other gear oils, while the castor oil having very less power loss compared to other types of gear oils.[4]

The castor oil is best alternative lubricant in reduction gear boxes for reducing power losses with low cost.[5]

The CFD analysis is very good tool to avoid costliest experiment processes and for finding out temperature of the new gear oil in gear box.[6]
