Hybrid Renewable Energy Systems: A Review

Pankaj Agarwal¹

¹Assistant Professor, Amity University Rajasthan

Abstract: Hybrid renewable energy systems (HRES) are becoming popular for remote area power generation applications due to advances in renewable energy technologies and subsequent rise in prices of petroleum products. A hybrid energy system usually consists of two or more renewable energy sources used together to provide increased system efficiency as well as greater balance in energy supply. The wind and solar energy are omnipresent, freely available, and environmental friendly. The wind energy systems may not be technically viable at all sites because of low wind speeds and being more unpredictable than solar energy. The combined utilization of these renewable energy sources are therefore becoming increasingly attractive. Economic aspects of these renewable energy technologies are sufficiently promising to include them for rising power generation capability in developing countries. These hybrid energy systems are becoming popular in remote area power generation applications due to advancements in renewable energy technologies and substantial rise in prices of petroleum products. Research and development efforts in solar, wind, and other renewable energy technologies are required to continue for, improving their performance, establishing techniques for accurately predicting their output and reliably integrating them with other conventional generating sources. The aim of this paper is to review the current state of the design, operation and control requirement of the stand-alone PV solar-wind hybrid energy systems with conventional backup source i.e. diesel or grid. This Paper also highlights the future developments, which have the potential to increase the economic attractiveness of such systems and their acceptance by the user

I. INTRODUCTION

Hybrid renewable energy systems (HRES) are becoming popular for remote area power generation applications due to advances in renewable energy technologies and subsequent rise in prices of petroleum products. A hybrid energy system usually consists of two or more renewable energy sources used together to provide increased system efficiency as well as greater balance in energy supply. One of the most promising applications of renewable energy technology is the installation of hybrid energy systems in remote areas, where the grid extensions costly and the cost of fuel increases drastically with the remoteness of the location. Recent research and development in Renewable energy sources have shown excellent potential, as a form of supplementary contribution to conventional power generation systems. Renewable energy sources, such as photovoltaic, wind energy, or small scale hydro, provide a realistic alternative to engine-driven generators for electricity generation in remote areas. It has been demonstrated that hybrid energy systems can significantly reduce the total lifecycle cost of stand alone power supplies in many situations, while at the same time providing a more reliable supply of electricity through the combination of energy sources.

Various hybrid energy systems have been installed in many countries over the last decade, resulting in the development of systems that can compete with conventional, fuel based remote area power supplies in many applications. In India, it is difficult to electrify the remote areas of Kumaon region and the odd small villages in Tehri Garwal district. It is uneconomical to provide grid power in these areas so hybrid renewable energy systems are very useful to electrify these remote villages. Various simulation programs are available, which allow the optimum sizing of hybrid energy systems. The recent state of art hybrid energy system technological development is the result of activities in a number of research areas, such as

- A. Advances in electrical power conversion through the availability of new power electronic semiconductor devices, have led to improved efficiency, system quality and reliability.
- B. Development of versatile hybrid energy system simulation software; continuing advances in the manufacturing process and improve efficiency of photovoltaic modules.
- C. The development of customized, automatic controllers, which improve the operation of hybrid energy systems and reduce maintenance requirements.
- D. Development of improved, deep-cycle, lead-acid batteries for renewable energy systems.
- E. Availability of more efficient and reliable AC and DC appliances, which can recover their additional cost over their extended operating lifetime.
- F. The task for the hybrid energy system controller is to control the interaction of various system components and control

International Journal for Research in Applied Science & Engineering Technology (IJRASET)

powerflow within the system to provide a stable and reliable source of energy. With the wide spread introduction of net-metering, the use of small isolated or grid connected hybrid energy systems is expected to grow tremendously in the near future. The aim of this paper is to review the current state of the design and operation of hybrid energy systems, and to present future developments, which will allow a further expansion of markets, both in industrialized and developing countries.

II. PRE-FEASIBILITY ANALYSIS OF HYBRID SYSTEM

Climatic conditions determine the availability and magnitude of wind and solar energy at particular site. Pre-feasibility studies are based on weather data [3] (wind speed, solar insolation) and load requirements for specific site. In order to calculate the performance of an existing system, or to predict energy consumption or energy generated from a system in the design stage, appropriate weather data is required. The global weather data could be obtained from internet and other sources like local metrological station. The global weather pattern is taken from NASA surface metrological station shown in Figs. 2 and 3. In Fig. 2 the red and yellow indicate high wind energy is available while the blue colors reflect lower wind energy potential zone. Fig. 3 shows the solar insolation level at different areas of the world. Wind and solar hybrid system can be designed with the help of these global weather patterns, for any location all over the world. Feasibility of hybrid PV/wind energy system strongly depends on solar radiation and wind energy potential available at the site. Various feasibility [38] and performance studies are reported to evaluate option of hybrid PV/wind energy systems [22, 50].

Photovoltaic array area, number of wind machines, and battery storage capacity play an important role in operation of hybrid PV/wind-diesel system while satisfying load [1]. The objective of lighting pathway at the project site can be achieved by making use of the wind, solar and hydro energy

sources. The information about local wind, a solar and hydro energy source indicates that a feasible hybrid energy system can be planned, modeled and designed for the above purpose. The collected data of the various energy sources was analyzed in order to plan for the structure of the system. This model also allows an optimal capacity of the hybrid energy system to be determined. Khan and Iqbal [22] discussed a primary design and pre-feasibility analysis of a hybrid energy system for a household in or around St. John's, Newfoundland. He collected 1-year wind speed, solar radiation and power consumption data of a house in St. John's, Newfoundland which was used for the feasibility study of a hybrid energy system.

International Journal for Research in Applied Science & Engineering Technology (IJRASET)

Fig.2. Global wind energy potential [75].

Wind power is one of the most efficient alternative energy sources. India is having a net potential of about 45000 MW only from 13 identified states. Wind resources can be exploited mainly in areas where wind power density is at least 400 W/m² at 30 m above the ground. An annual mean wind power density greater than 200 W/m² (watts per square meter) at 50-m height has been recorded at 211 wind monitoring stations, covering 13 states and union territories. India’s wind power potential has been assessed at 45,000 MW. A capacity of 15700MW has been installed. Solar power has so far played an almost non-existent role in the Indian energy mix. The grid-connected capacity in the country now stands at 481.48 MW, while the total solar energy potential has been estimated at 50,000 MW. Most parts of India have 300 – 330 sunny days in a year, which is equivalent to over 5000 trillion kWh per year. Average solar incidence stands at a robust 4 – 7 kWh/sqmr/day.

Table 1. Estimation of installable wind power potential at 80 m level

Wind potential has yet to be validated with actual measurements.

Estimation is based on meso scale modeling (Indian Wind Atlas).

As actual land assessment is not done on a conservative consideration 2 % land availability for all states except Himalayan & North eastern states, Andaman Nicobar Islands and Poor windy states has been assumed. In other area 0.5% land availability has been assumed.

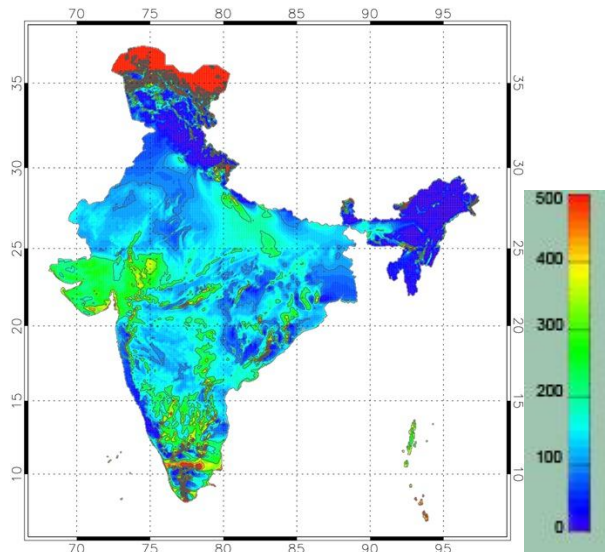

Fig3. Wind power density map at 80 m level[76]

III. UNIT SIZING AND OPTIMIZATION

After pre-feasibility study the selection of proper sizing of equipment is made based on weather data and maximum capacity. The unit sizing of integrated power system plays an important role in deciding the reliability and economy of the system. In this section, study by the different researchers discussing different methods to determine the wind generator capacity and the number of PV panels and other sources and number of battery needed for the stand-alone system is reviewed. Using the measured data of solar and wind energy at given location, author employ a simple graphical construction to determine the optimum configuration of the two generators that satisfies the energy demand of the user throughout the year. Katti and Khedkar [9] develop the algorithm uses hourly average wind speed, insolation, and power demand to determine the wind/PV generation capacities required to meet the demand without loss of power supply probability (LPSP). Elhadidy and Shaahid [24–26] calculated optimum battery storage size for hybrid wind energy system by studying an impact of variation of battery storage capacity on hybrid power generation. Tradeoff between size

International Journal for Research in Applied Science & Engineering Technology (IJRASET)

of the storage capacity and diesel power required for the load, assuming a constant wind power output, was also reported by the authors. In 2006, Koutroulis et al. [19] presented a methodology for optimizing [31] of stand-alone PV/WG systems using genetic algorithms. They applied design approach of a power generation system, which supplies a residential household. Optimum size of hybrid PV/wind energy system can be calculated on an hourly basis [17] or on the basis of daily average power per month, the day of minimum PV power per month, and the day of minimum wind power per month. Performance of hybrid PV/wind energy system was compared on hourly basis; by fixing the capacity of wind generators, yearly loss of load probability (LOLP) with different capacity of PV array and battery bank were calculated. Trade off curve between the battery bank and PV array capacity for given LOLP helps to find optimum configuration at least cost. They employ a linear programming techniques [34] to minimize the average production cost of electricity while meeting the load requirements in a reliable manner, and takes environmental factors into consideration both in the design and operation phases.

Yang [8] developed a novel optimization sizing model for hybrid solar-wind power generation system. To optimize the capacity sizes [29] of different components of hybrid solar-wind power generation systems employing a battery bank, the authors also calculated battery size requirements to achieve desired level of autonomy by using system performance simulation model. It is observed that for achieving high autonomy, a backup generator is required and in turn reduces battery storage capacity. Hancock et al. [61] discussed the approach to optimize hybrid PV/wind/battery system with conventional power plant and calculated optimal system configuration on the basis of Lifecycle cost.

National Renewable Energy Laboratory (NREL)'s, Hybrid Optimization Model for Electric Renewable (HOMER version 2.19) [73] has been used as the sizing and optimization software tool [72]. It contains a number of energy component models and evaluates suitable technology options based on cost and availability of resources. Analysis with HOMER requires information on resources, economic constraints, and control methods. It also requires inputs on component types, their numbers, costs, efficiency, longevity, etc. Sensitivity analysis could be done with variables having a range of values instead of a specific number.

IV. MODELING OF HYBRID RENEWABLE ENERGY SYSTEM (HRES) COMPONENTS

Literature review reveals that over the last decades, HRES applications are growing rapidly and HRES technology has proven its competitiveness for remote area applications. It is observed that approximately 90% of studies reported are on design/economic aspects of HRES. However, fewer studies were reported on control of HRES. Utility interactive HRES [68] has yet not gained the popularity. It is expected that within the next few years HRES becomes competitive with utility grid power for wide spread distributed applications. Hence, there is a need to investigate potential and performance of PV and wind energy system to calculate level of penetration in existing networks of developed or developing countries in order to improve quality of power supply. The simulation results prove the operating principle, feasibility and reliability of this proposed system. Solar/diesel/battery hybrid power systems [23,67] have been modeled for the electrification of typical rural households and schools in remote areas.

V. FUTURE TRENDS FOR DESIGN AND OPERATION OF HYBRID ENERGY SYSTEM

This system can be considered for sustainable hybrid energy system, designed on two modes. One is stand-alone and other is grid-assisted mode. In stand-alone mode, it draws power from the wind-solar hybrid energy system. In the grid-assisted mode, when the hybrid system is unable to feed the power, it automatically takes the grid power. If the site-specific data is not available, one may use nearest meteorological station data in designing the system. The system voltage variation, the frequency, waveform and power factor at the time of grid connection, must be maintained within the limits. One can improve the power quality depending upon the local conditions. Hybrid energy flow is controlled using power electronic converters. This energy would be useful in many applications such as ship power systems, electric hybrid vehicles, telecommunication industries, rural electrification etc.

Further R&D improvements in solar PV and wind technologies will reduce the cost of renewable energy sources. The cost of conventional energy resources is increasing every year. This system is going to be economical in future. Besides the cost, the environmental benefits are likely to facilitate the widespread use and acceptance of these systems

VI. CONCLUSIONS

The hybrid energy systems are recognized as a viable alternative to grid supply or conventional, fuel-based, remote area power supplies all over the world. The review reveals that, renewable energy based low emission hybrid systems are not cost competitive

International Journal for Research in Applied Science & Engineering Technology (IJRASET)

against conventional fossil fuel power systems. However, the need for cleaner power and improvements in alternative energy technologies bear good potential for widespread use of such systems. Moreover, the rural households in industrialized and less developed countries attach high value to be liable, limited supply of electricity. Community facilities such as rural hospitals, schools, telecommunication and water pumping stations can contribute significantly to the welfare of people and rural development. While it is recognized that technology can only be one aspect of community development, the renewable energy systems have demonstrated the potential to provide support in some of the basic infrastructure needs in remote and urban areas for different applications. Although the cost reduction and technological development of hybrid energy systems in recent years has been encouraging, still they remain an expensive source of power. To allow the widespread application of this emerging technology, there is a need for further R&D improvement in solar PV and wind technologies that can reduce the cost of hybrid system. The cost of conventional energy resources is increasing every year, but the receding trend in the cost of renewable energy technologies because of its widespread use is an encouraging factor, projecting RES system an economical means of power generation in future for many standalone applications.
